Northeastern Pacific Albacore Survey
Part 2. Oceanographic and Meteorological Observations

SPECIAL SCIENTIFIC REPORT--- FISHERIES No. 315

UNITED STATES DEPARTMENT OF THE INTERIOR
FISH AND WILDLIFE SERVICE

Explanatory Note

The series embodies results of investigations, usually of restricted scope, intended to aid or direct management or utilization practices and as guides for administrative or legislative action. It is issued in limited quantities for the official use of Federal, State or cooperating Agencies and in processed form for economy and to avoid delay in publication.

Special Scientific Report--Fisheries No. 315

WASHINGTON: JULY 1959

ABSTRACT

Oceanographic and meteorological observations obtained aboard the United States Fish and Wildlife Service research vessels Hugh M. Smith and John R. Manning during Operation NEPAS in 1957 and en route to and from Hawaii are presented in this report. It also contains a summary of the limited oceanographic observations made by the eight contract vessels. Data are published without analysis or interpretation to make them available to other investigations in the north PACIFIC area.

The field and laboratory procedures are briefly described. The vertical and horizontal distribution of temperature, salinity, dissolved oxygen, and inorganic phosphate off the coasts of California Oregon, and Washington are presented in tables, station curves, and surface plots. Secchi disc, Forel color, and photometer measurements are tabulated by vessel.

Biological Laboratory[2/]
Honolulu, Hawaii

The Northeastern Pacific Albacore Survey (NEPAS) was a survey of the abundance and distribution of the albacore, Germo alalunga (Bonnaterre), conducted in a band approximately 350 miles wide off the coasts of northern California, Oregon, and Washington between 35°N. and 47°N. latitude from July 22 to August 1, 1957. Meteorological and oceanographic observations, the data from which are presented in this report, accompanied the biological sampling program. It was conducted by the Honolulu Biological Laboratory, Bureau of Commercial Fisheries as part of their Saltonstall-Kennedy albacore project in cooperation with fishery research agencies of California, Oregon, and Washington. The Pacific Marine Fisheries Commission provided liaison among the cooperating agencies.

A total of 11 vessels participated in the survey. The Fish and Wildlife Service research vessel Hugh M. Smith acted as coordinating vessel and conducted most of the detailed oceanographic observations (see fig. 1). The Fish and Wildlife Service research vessel John R. Manning made a preliminary fishing survey of the NEPAS area and did additional fishing in the areas where the contract vessels reported their better catches. The Manning also made a limited number of oceanographic observations. Her track is shown in figure 2. Nine contract vessels started the trolling survey but only seven completed their assigned tracks (see fig. 3). The other two vessels were forced to withdraw before they had contributed materially to the survey. The tracks of the seven contract vessels completing the survey are shown in the frontispiece. The owners, the observers and the agency providing the observer are listed in table 1.

This report contains the oceanographic and meteorological observations taken aboard the Smith and Manning and the surface observations made by the contract vessels. The field and laboratory procedures are also described. The biological data collected during the survey, except for the plankton, have already been reported by Graham (1959). The plankton data will be contained in a later report.

FIELD PROCEDURES

Water Sampling Program

Seventy oceanographic stations were occupied by the Hugh M. Smith at the positions shown in figure 1 and listed in table 2. From Honolulu to 38°35'N., 142°28'W. and from 33°36'N., 126°30'W. to Honolulu, Nansen bottle casts were made at 0800 and 2000 zone time (total 30). Only one cast was made each day (total 40) in the survey area since the vessel usually hove to at night, in order to make a continuous trolling survey along her track. Trolling was conducted at 6.5 knots during the day.

At each oceanographic station a cast of 13 Nansen bottles was made to approximately 1200 meters. The spacing of the bottles in the upper 300 meters was determined by the characteristics of a bathythermograph trace obtained just prior to the station. The remaining bottles were placed at standard depths. Paired protected reversing thermometers were attached to each bottle. All but the upper four bottles (those at approximately 100 meters or less) carried an unprotected reversing thermometer.

Water samples were drawn from each Nansen bottle for salinity, oxygen, and inorganic phosphate determinations. At stations 99, 139, 147, and 156 additional samples were drawn for boron analysis. These samples were shipped to Mr. James Gast of the University of Washington for analysis.

[1/] Presently employed at the Bureau of Commercial Fisheries Biological Laboratory, Seattle, Washington.

[2/] Formerly the Pacific Oceanic Fishery Investigations.

Surface samples for determination of salinity and inorganic phosphate were taken at most of the off-station BT casts. Surface salinity samples were taken by the Hugh M. Smith at approximately 30-mile intervals from Honolulu to the survey area, from the survey area to Honolulu, and surface salinity and inorganic phosphate samples were taken at each off-station BT cast in the survey area. Salinity and inorganic phosphate samples were taken by the John R. Manning at approximately 60-mile intervals from Honolulu to Astoria and at approximately 30-mile intervals from Astoria to 30°N. latitude (see fig. 2 for her track).

Bathythermograph Observations

A 900-ft. BT cast was made from the Hugh M. Smith, before and after each Nansen bottle cast. When surface temperatures were 66°F. or less, BT casts were made at intervals of not more than 15 miles, when abrupt surface temperature changes were indicated on the recording thermograph, and each time albacore were landed if one hour had elapsed since the previous lowering. At surface temperatures greater than 66°F. two BT's were taken between oceanographic stations. The positions of and observations made at the Smith's BT casts are given in table 3.

From the John R. Manning, 900-ft. BT casts were made at approximately 30-mile intervals and also before and after each gill-net station. From Astoria, Oregon, to about 30°N. latitude, 450-ft. BT casts were also made at 0300 zone time on the nights when the gill nets were set. The positions of and the observations made at the Manning's BT casts are given in table 4.

The BT slides were processed by the United States Navy Hydrographic Office and the data were used to construct the temperature cross sections along the vessel tracks; Hugh M. Smith in figures 4 to 16 and John R. Manning in figures 17 to 27. The portion of the tracks included in each of the cross sections is indicated by the letters on the vessel tracks (figs. 1 and 2).

Meteorological Observations

Synoptic weather observations as outlined in the United States Weather Bureau Circular M (1956) were made aboard both our vessels at 0000, 0600, 1200, and 1800 GCT and transmitted to the United States Weather Bureau at Honolulu or San Francisco, whenever radio conditions permitted. A summary of these observations as recorded on United States Weather Bureau Form 1210F are listed in tables 5 (Smith) and 6 (Manning).

Subsurface Illumination and Water Color Measurements

Measurements of the percentage of subsurface illumination relative to that at the sea surface were made from the John R. Manning at 75 stations. Measurements were made not earlier than two hours after sunrise and not later than two hours before sunset. A Schueler photometer, which has been described by Callaway (1957), was used. The response curve of the photometer matched the standard curve of the International Commission on Illumination which has a spectral range of 430 to 700 millimicrons and a peak sensitivity at 550 millimicrons[3/]. The total incident light was estimated in foot candles with a standard camera exposure meter. Because the cable to the sea cell broke repeatedly, the 1-percent level of illumination was measured only occasionally. Some values at the 50-percent and 10-percent levels are also open to question because the shadow of the ship's hull and rigging interfered. The results are given in table 7.

Secchi disc and Forel water color observations were made from both the Manning and Smith. The Secchi disc observations were made in the manner described in the United States Navy Hydrographic Office Publication 607 (1955). Water color as it appeared according to Forel's scale against the Secchi disc background was also made at each lowering. Aboard the Smith these observations were made at 0800 zone time while operating outside the NEPAS area. Within the area they were made daily at 1300 zone time and after each albacore school had been worked when light and sea conditions were suitable. The Smith's results have been included in table 2. Aboard the Manning they were made simultaneously with the photometer measurements and have been included in table 7.

Observations by the Charter Vessels

Each charter vessel was provided with bucket thermometer and a Secchi disc. They made surface temperature observations to the nearest half degree every four hours while underway and after each albacore school had been worked. The observed temperatures are not included in this report but have been used in constructing the surface temperature plot, figure 28.

3/ Weston Photronic Photoelectric Cells, Weston Electrical Instrument Corporation Circular B-27-A, February 1949.

Secchi disc and cloud cover observations were made each day at local noon. The results are listed in table 8.

LABORATORY PROCEDURES

Chemistry

Salinity samples were placed in glass bottles and sealed with paraffin-impregnated corks and screw caps. Double titrations were made in the Honolulu laboratory using a modification of the Knudsen method. This modification (Van Landingham 1957) results in a stoichiometric end point and involves the use of an adsorption indicator, phenosafranin, in the presence of starch as a protective colloid. The surface salinities at the off-station BT's are given in tables 3 (Smith) and 4 (Manning) and those for the Smith's oceanographic stations in table 9. A plot of the surface salinity is shown in figure 29.

Dissolved oxygen analyses were performed aboard the Hugh M. Smith by the Winkler method. These results are also contained in table 9.

The inorganic phosphate samples were placed in screw-cap culture tubes, sealed with plastic tape, and quick, dry-frozen for analysis ashore. Analysis was performed in the Honolulu laboratory using a modification of Denige's method developed by Van Landingham[4/]. The values for the surface samples taken at the off-station BT's are included in tables 3 (Smith) and 4 (Manning) and the values for various depths at the Smith's oceanographic stations 19 through 139 are listed in table 9.

Oceanographic Processing

Processing of the oceanographic data was performed at the Honolulu laboratory under the supervision of Mrs. M. L. Godfrey.

The presentation of the data is similar to that of King et al. (1957) in that only the observed station data are listed (table 9). In order to facilitate further use of the data, graphs showing the complete set of curves are also given for each station.

In the upper 300 meters one of the BT traces taken at the station was used as a guide in constructing the temperature depth curve for the reversing thermometer readings. To insure continuity among the various parameters, salinity and oxygen are shown as curves plotted against temperature rather than depth (Montgomery 1954). Station to station continuity was maintained by utilizing the curves for adjacent stations in constructing the curves for each parameter.

Although the inorganic phosphate data are included in the tabulations, they have been omitted from the station curves. This was because values in the vicinity of the oxygen minimum seemed to vary erratically. This will require further study and comparison with data from other sources to determine whether the variations are real or may have been caused by handling of the frozen samples.

Isopleths of thermosteric anomaly are shown on each station graph in lieu of the customary isopleths of sigma-t. This was done to permit the computation of dynamic heights by the method of Montgomery and Wooster (1954). This method differs from the conventional method (LaFond 1951) in that the pressure terms of the specific volume anomaly are neglected. The surface heights (geostrophic currents) relative to the 1,000 decibar level are shown in figure 30 to indicate the general circulation through the area.

[1/] All columns in USWB 1210-F are not included here. Those deleted are:

Column 2 Day of week
" 3 Octant
" 13 Barometer as read
" 14 Barometer as corrected
" 17 Air temperature, °F.
Column 23 Course of ship
" 24 Speed of ship
" 31 Diff. sea-air, °F.
" 32 Dew point, °F.

Table 9.--Station curves and observed oceanographic data
Hugh M. Smith cruise 40

Notes on Oceanographic Station Curves

Thermosteric anomaly (oblique lines) are in centiliters per ton (Montgomery 1954). Where temperatures of paired thermometers differed by more than 0.05°C. below 300 m. or more 0.10°C. above 300 m., both values are plotted and designated by the symbol ⩓. The other variables are plotted for each of the temperature values, see station 12. When the station curve is not drawn through a plotted value, it is considered a gross error and not used.

Explanatory code for station curves:

⩓ Reversing thermometer temperatures °C.

• BT temperature °C.

⊡ Salinity ‰.

▽ Dissolved oxygen ml./L.

⊙ Inorganic phosphate µg. at./L.

Notes on Observed Oceanographic Data

Where more than one cast was made on a station, they are separated by a horizontal line. The cast number is indicated by a Roman numeral in the margin.

Where the corrected, paired, protected thermometer readings differed by more than 0.05°C. below 300 m. or more than 0.10°C. above 300 m., both temperature values are tabulated and the depth and salinity are repeated. Delta-t calculated using each temperature value is carried.

Explanatory code for tabulated data:

NG - The value or line is in error and is discarded.

NS - This water sample was lost.

Q - The value seems questionable but was used in construction of the station curve.

P - The value is questionable and while carried was not used in drawing the station curve.
