Raymond E. Anas, and Douglas G. Chapman

ABSTRACT

A total of 48,980 male seals were killed on the Pribilof Islands in 1964. Age classification in percent was: 8, 60, 27, and 5, ages 2-5. The peak of the kill occurred 27-31 July. Predicted kills of 3- and 4-year-old males on St. Paul Island by 5 August were 24,000 and 13,000; actual kills were 22,203 and 10,509. Harem and idle bull counts were 11,074 and 8,584. Of 16,452 female seals killed, 72 percent were in ages 2-5 and 28 percent were age 6 and older. Of 147 3-year-old females examined, all were nulliparous; 3 of 73 4-year-old females were primiparous and post partum. Recoveries of seals marked as pups included 4,205 with tags and 1,890 with checkmarks only. A total of 302 seals selected and tagged as yearlings in previous years and 45 Soviet-tagged seals were killed. A total of 24,991 pups were tagged and checkmarked. Surveys of yearlings tagged as pups in 1963 were made to provide an index to survival from birth to age 1. Land pup mortality was 25,042. From 4-year-old male tag recoveries, there were an estimated 614,580 pups alive at the time of tagging in 1960. From 3-year-old male tag recoveries, there were 494,724 pups in 1961. Pup populations estimated from female data were 604,546 for 1960 and 473,131 for 1961. Recoveries of seals tagged as yearlings indicated that 80,211 male seals of the 1961 year class survived to age 1. Marked to unmarked ratios yielded an estimate of 353,000 pups born on the Pribilof Islands in 1964. Total counts of live pups on some rookeries supported this estimate. Tagged male and female pups weighed 1.10 and 0.92 kilograms less than untagged males and females. A total of 1,077 skins from males and females were collected for experimental use in relating economic value to age and sex. The predicted male kill as of 5 August 1965 is 4,000 ages 2 and 5, 33,000 age 3, and 16,000 age 4.

INTRODUCTION

Complete protection of female seals was one of the principles followed in restoring the reduced Pribilof seal population, after signing of the Fur Seal Convention of 1911. The steady growth of the population from 1911 to about 1940 illustrated the effectiveness of this principle. After 1940 the failure of the kill of males and the number of harem bulls to increase raised doubts about the population figures in use and the wisdom of continuing current management methods indefinitely. The first of continuing population studies (Kenyon, Scheffer, and Chapman, 1954) demonstrated that the Pribilof population was far smaller than had been calculated from a constant increase percentage. The decreased growth rate suggested that the seal population was being restrained by one or more unknown factors of its environment. A logical succeeding step was a recommendation that some females be killed since they did not contribute to an increased population size or kill. Time was needed to bring about this abrupt change in the traditional standards for killing seals. The first change was made in 1954 when all females found in the round-up of males were purposely killed. Surprisingly, only 540 females were taken by the end of the male kill on 27 July, about 300 more than were usually taken accidentally with males.

The plan to take females was developed further in 1955 by discussions of U.S. and Japanese

Note.--Alton Y. Roppel and Ancel M. Johnson, Wildlife Biologists (Research), and Raymond E. Anas, Fishery Biologist (Research), Bureau of Commercial Fisheries Marine Mammal Biological Laboratory, U.S. Fish and Wildlife Service, Seattle, Wash.; and Douglas G. Chapman, Laboratory of Statistical Research, University of Washington, Seattle, Wash.

statisticians at the conference to negotiate a new fur seal convention. Some assumptions used in preparing a plan of action were:

1. The number of females in the Pribilof population was greater than needed to provide a maximum sustained yield, and unless reduced the population would begin to exhibit more drastic fluctuations.
2. After reduction of the population to a calculated sustained yield point, some females would be available in the harvest each year.
3. Improvement in the productivity of the population could be measured most quickly by observing the change in land mortality of pups and in the pregnancy rate of females. It would also be observed later in the number of returning seals.

By fall of 1963, population estimates, supplemented by observation of the reduced area of some rookeries and the fewer females on hauling grounds and rookery fringes, indicated that the number of females was sufficiently reduced. Both killing and natural mortality contributed to the lower population.

Beginning in 1964 the number of females to be taken is the surplus recruitment. This is determined by calculation and by availability.

The period of reduction was more extended than was desirable and the total amount of reduction was made less clear by fluctuating natural mortality. Methods of estimating populations and monitoring mortality and reproduction have been improved or made more specific. There is evidence now that the population level was lower than calculated when the experiment was planned.

As it enters its second phase, the experiment promises to have interesting and useful results even if the economic return from the fur seals is not increased. Results, such as lower population estimates and reduced land mortality, are beginning to accumulate, but it is too early to show how these changes are related to reduction of the population. The manipulation of seal numbers required by the experiment is capable of producing concrete evidence on which sound management principles can be based.

The 1964 field season on the Pribilof Islands extended from June to October. Arrivals, departures, and affiliations of research workers follows:

[1]Temporary employee.

Shoichi Tanaka spent the period from 20 July to 10 August on the Pribilof Islands observing fur seal research, seal killing, and skin processing. Tanaka represents the Government of Japan, Tokai Regional Fisheries Research Laboratory. His visit was arranged under the provisions of the Interim Convention on Conservation of North Pacific Fur Seals.

Allison M. Craig and assistant Christopher Craig were on St. Paul Island 10-31 August conducting experiments on the effects of pituitary extracts of seals on the reproductive organs of captive female fur seal pups. Miss Craig represents the Government of Canada through the Fisheries Research Board of Canada. This body supports fur seal research at the University of British Columbia.

Roger Spencer, Professor of Veterinary Medicine at Washington State University, was on St. Paul Island from 28 July to 10 August. He assisted the staff veterinarian with studies of fur seal pathology and prepared an appraisal of seal mortality investigations.

POPULATION

Males

Age Classification.--The male seals killed on the Pribilof Islands in 1964 are classified by age in appendix tables 5, 6, 7, and 8. All available males from 42 inches, tip of nose to tip of tail, to those having a mane were included in the kill. The mane, a secondary sex characteristic composed of long silver-colored guard hairs on the neck, appears first on some 5-year-olds. At age 6, most males have a developing mane.

Age classification of the male kill was determined from a sample of 5,140 canine teeth collected on St. Paul Island and from 1,587 collected on St. George Island. Normally, 10 percent of the males killed are sampled for their canine teeth. The size of the tooth sample, however, is increased when the number of seals killed on a rookery from one drive is below certain levels. The following sampling schedule is used: 10 percent of a kill of 300 or more; 20 percent of 100 to 300; and 30 percent or more of 100 or fewer animals.

The minimum length limit of 42 inches was removed for 8 days beginning 17 July so that all available 2-year-old males could be taken. Though only a small proportion of this age class is on land in late July a complete kill of those that are available may provide information useful for forecasting the size of the 3-year-old kill the following year. Twenty percent of all the males killed were sampled for age and body length during the 8-day period.

The peak of the kill occurred during round 7 (27-31 July) when 6,550 males were taken on St. Paul Island (fig. 1). The percent cumulative kill, by date, age, and island is shown in figure 2.

Table 1 shows the kill of male seals by year class for the years 1947-62. Tables 2 and 3 illustrate the kill of 3- and 4-year-old male seals at various dates for 1954-64, and the cumulative numbers of males killed each year from 1955 to 1964, St. Paul Island.

Bull Counts.--Harem and idle bulls decreased for the third successive year. The 1964 bull counts by island and by rookery are given in table 4, and all bull counts since 1911 are presented in appendix table 9.

Harem bulls on St. Paul Island decreased by 1.4 percent of the 1963 count; those on St. George Island decreased by 4.0 percent. The magnitude of the percent decrease from 1963 to 1964 was less than that from 1962 to 1963 when St. Paul Island had 10.9 percent fewer and St. George had 11.6 percent fewer harem bulls. The total number of harem bulls on the Pribilof Islands was 98 percent of the 1963 count.

The idle bulls on St. Paul Island decreased 7.3 percent from 1963; those on St. George Island decreased by 21.2 percent. The magnitude of the percent decrease was also less than that for the 1962-63 counts when St. Paul Island had 16.0 percent fewer and St. George Island had 28.7 percent fewer idle bulls. The total number of idle bulls on the Pribilof Islands was 90 percent of the 1963 count.

Females

Age Classification.--The female seals killed on the Pribilof Islands in 1964 are classified by age in appendix tables 10, 11, 12, and 13. Year class contributions to the female kills on the Pribilof Islands are given in table 5 for the years 1939-63. Table 6 shows the percent age composition of female seals sampled from the kills on the Pribilof Islands from 1958 to 1964.

Because the need to reduce the number of females has ended, most old females appearing in the drives in 1964 were allowed to escape. In general, only females having black or a mixture of black and white vibrissae were killed. Selection on this basis roughly restricts the kill of this sex to ages 2-5, or those having the highest quality skins. Most females 6 years old and older have white vibrissae.

The source of females killed on St. Paul Island in 1964 was noted, that is, whether from traditional male hauling grounds, rookery fringes, or from mixed areas. The age composition of females taken from these three areas is given in table 7. Behind some of the rookeries are areas on which few animals appear until August, or after the general breeding season. Because seals using these areas may be a mixture of animals from the rookery and from the hauling ground, they are classified as coming from a mixed area. As in 1963, there was little difference in the age composition of females taken from the three areas.

Reproduction.--The genital tracts from 147 3-year-old and 73 4-year-old females taken in the kill on St. Paul Island in 1964 were collected and preserved for a detailed study to be made later. A gross examination of the genital tracts revealed that none of the 3-year-old females had given birth to pups in 1964 or previously; three 4-year-old females were primiparous and post partum.

Soviet tagged females bearing tags M-13487, E-17100, and C-54750 (ages 2, 3, and 4,

respectively) were taken on St. Paul Island in 1964. The genital tracts of these females showed that all were nulliparous and that none had ovulated during the summer.

Tag Recoveries and Tagging

Tag Recoveries.--Except for a few tagged animals taken for experimental use, tagged male and female seals were not killed purposely, but rather, were taken only if they were within the limits described on pages 3 and 8 of this report.

A total of 4,205 tags were recovered from seals tagged as pups; 1,890 checkmarks from seals that had lost their tags were recorded. These data are summarized in table 8 by sex, age, and island, and are given in more detail in appendix table 14. The homing tendency of tagged male and female seals is shown in table 9 by age and in table 10 by rookery.

A total of 302 seals selected and tagged as yearlings on St. Paul Island in 1961 (M-series), 1962 (N-series), and 1963 (O-series) were recovered on the Pribilof Islands in 1964. The recovery information is given in tables 11 and 12.

Information on 45 Soviet-tagged seals killed on the Pribilof Islands in 1964 is given in table 13 and in appendix table 15.

Tagging--Pups.--The number of pups tagged in 1963 is listed in table 14 by rookery, and a record of pups tagged on the Pribilof Islands since 1941 is given in appendix table 16. Tag and checkmark locations on pups tagged since 1947 are shown in appendix figure 1.

Of 24,991 Q-series tags attached to pups in 1964, 19,998 were used on St. Paul Island and 4,993 on St. George Island. This was the second year of a 2-year program designed to determine the influence, if any, of age of pups when tagged on survival. As in 1963, half of the pups on St. Paul Island were tagged in late August and half in late September. Mortality rates of the two groups will be compared in 1967 when the survivors return at age 3.

All tags used in 1963 and in August 1964 were attached at the hairline of the front flipper. Tags used in late September 1964 were attached about 2 inches toward the tip of the flipper from the hairline. At this point, tags will not interfere with muscles and blood vessels as they do when attached at the hairline.

Under the reduced tagging program, a crew of 10-12 men is adequate in that this number is large enough to complete tagging on the largest rookeries in 1 day, yet small enough to permit quality in tagging and gentler handling of pups.

Survey--Yearlings.--Surveys of certain areas on St. Paul Island were begun in 1963

and continued in 1964 to determine the relative number of known-age yearling seals on land in late September and early October. If the number of yearlings counted on land during the sampling period is related to the return of the age class 2 years later, yearling surveys will be useful as a method for predicting the kill of 3-year-old males. An additional 3 or 4 years of data are necessary, however, before it can be determined if such a relationship exists.

The results of the yearling surveys in 1964 are given in table 15. Methods and survey areas used have been described previously (Roppel, Johnson, and Chapman, 1963). Among known-age yearlings captured during the surveys in 1963 and 1964 and during yearling tagging in 1961, 1962, and 1963, males have outnumbered females by as much as 15 to 1.

[1] Seals tagged as pups in 1963.

Mortality

Pup mortality in 1964 decreased by 34 percent of the 1963 count on St. Paul Island and by 52 percent on St. George Island. The 1964 count of dead pups was the lowest since the beginning of complete counts in 1953. The data for both islands are given in table 16 by rookery, and dead-pup counts made since 1941 are presented in appendix table 17.

Population Estimates

Estimates of the pup population are currently derived from three sources: (1) The tag recoveries and tag loss identifications in the kill; (2) the ratio of marked to unmarked in samples of live pups; and (3) total counts of live pups on three rookeries and a portion of a fourth. In previous years the tag-lost to tagged ratio on St. George Island was changed to correspond to the ratio observed on St. Paul Island if there was an appreciable difference in the ratios observed on the two islands. This procedure was not used this year.

In 1964, for the first time, recoveries of tags from males tagged as yearlings were sufficiently numerous to form a basis for

estimating the number of seals from a year class alive at age 1.

Estimates of the Pup Population From the Recovery of Tagged Males.--During the period 17-19 July, the tag-lost recoveries on St. Paul Island were recorded incorrectly; therefore, the number of tag-lost for this period was estimated by the tag-lost to tagged ratio observed during the remainder of the male kill. Also, the tag-lost to tagged ratio for 2-year-old males was much higher on St. Paul Island than on St. George Island, 0.65 and 0.30, respectively (table 8).

Recent estimates of the pup population are lower than those of the mid- and late-1950's (tables 17, 18, and 19).

Estimates of the Pup Population From the Recovery of Tagged Females.--Two features should be noted in the tag recoveries from females (table 8). First, the tag-lost to tagged ratio is unrealistically high for 2-year-old females on St. Paul Island--this is probably the result of recording tag loss from 6-year-olds as that from 2-year-olds. Secondly, the tag-lost to tagged ratio for all ages is higher on St. Paul Island than on St. George Island.

Estimates of the 1960 and 1961 year classes based on the recovery of tagged females and of tagged males were similar (tables 17 and 20). The high but unreal rate of tag loss recorded on St. Paul Island for 2-year-olds resulted in the low estimate for that year class and a high estimate for the 1958 year class. Estimates based on the recoveries from tagged females have generally been more erratic than those based on recoveries from tagged males.

Estimated Number of Yearling Males, 1961 Year Class.--Length was first used as a basis for selecting yearling animals for tagging in 1962 (Roppel, Johnson, Bauer, Chapman, and Wilke, 1963). Of those tagged, most were yearlings, some were 2 years old and, for females at least, some were 3 years old. The ages of animals tagged as yearlings are determined from tooth ridge counts when the seals are taken in the kill; thus, the proportion older than 1 at the time of tagging can be estimated. For example, 2 of 46 males tagged as yearlings in 1962 and recovered from the kill in 1963 were older than 1 at the time of tagging. In 1964, 222 males tagged as yearlings were recovered from the kill; the ages of 7 had been incorrectly determined at the time of tagging. Thus, 3.4 percent of the males recovered were older than 1 at the time of tagging. On this basis, 600 or 96.6 percent of the 621 males selected and tagged as yearlings in 1962 on the basis of body length were actually yearlings. The estimate of the error (3.4 percent) in determining ages, however, is probably too high as seals older than 1 at the time of tagging have subsequently been available in the kill as 3- and 4-year-olds, while those that were age 1 have to date been available only as 2- and 3-year-olds. The probability of tagged seals being taken in the kill is greater at ages 3 and 4 than at ages 2 and 3. The error of 3.4 percent, if too high, would inflate the estimates of the number of yearlings.

Table 17.--Estimates of the pup population based on tag recoveries from males, Pribilof Islands, Alaska, year classes 1959-62

Year class	Killed 1 July to 7 August 1964 (n)	Tagged (t)	Tagged and tag-lost seals recovered (s)	Population estimate (N)
	Number	Number	Number	Number
1959	2,252	49,881	201	556,357
1960	13,073	59,981	1,275	614,580
1961	28,827	49,921	2,908	494,724
1962	2,726	49,908	364	372,882

n = number of males killed from each year class, 1 July through 7 August 1964.
t = number of tags applied to each year class.
s = number of tagged and tag-lost males recovered from each year class, 1 July through 7 August 1964.
N = estimated number of pups in each year class at time of tagging; $\frac{(n+1)(t+1)}{(s+1)}$.

Table 18.--Estimates of the pup population based on recoveries of tagged male seals at ages 3 and 4, Pribilof Islands, Alaska, year classes 1958-61

Year class	Killed at ages 3 and 4 (n)	Tagged (t)	Tagged and tag-lost seals recovered (s)	Population estimate (N)
	Number	Number	Number	Number
1958	74,890	49,917	5,409	691,018
1959	48,596	49,881	3,324	729,057
1960	31,059	59,981	3,279	568,000
1961	[1] 28,827	49,921	[1] 2,908	494,724

[1] Age 3 only.

n = number of 3- and 4-year-old males killed from each year class. Males accidentally taken during the female kill are excluded.
t = number of tags applied to each year class.
s = number of 3- and 4-year-old tagged and tag-lost males recovered from each year class during the male kill.
N = estimated number of pups in each year class at time of tagging; $\frac{(n+1)(t+1)}{(s+1)}$

Table 19.--Estimated number of pups born, Pribilof Islands, Alaska, year classes 1951-62 [1]

Year class	Estimated number of pups alive at time of tagging	Dead-pup count	Estimated number of pups born
1951	484,000	86,000	570,000
1952	529,000	87,000	616,000
1953	704,000	91,000	795,000
1954	727,000	111,000	838,000
1955	778,000	90,000	868,000
1956	872,000	120,000	992,000
1957	637,000	75,000	712,000
1958	691,000	38,000	729,000
1959	729,000	49,000	778,000
1960	[2] 568,000	75,000	643,000
1961	[2] 495,000	71,000	566,000
1962	[3] 373,000	54,000	427,000

[1] See footnote 2, p. 29, for source of estimates 1951-59.
[2] From table 18, this report.
[3] From table 17, p. 16, this report.

Table 20.--Estimates of the pup populations based on tag recoveries from females, Pribilof Islands, Alaska, year classes 1958-62

Year class	Killed 14-29 August (n)	Tagged (t)	Tagged and tag-lost seals recovered (s)	Population estimate (N)
	Number	Number	Number	Number
1958	1,822	49,917	94	957,900
1959	3,543	49,881	228	775,359
1960	3,325	59,981	329	604,546
1961	3,354	49,921	353	473,131
1962	346	49,908	108	158,881

n = number of females killed from each year class, 14-29 August 1964.

t = number of tags applied to each year class.

s = number of tagged and tag-lost seals recovered from each year class, 14-29 August 1964.

N = estimated number of pups at time of tagging; $\frac{(n+1)(t+1)}{(s+1)}$.

Using the above information in the modified Petersen formula, the number of yearling males born in 1961 and still living at the time of tagging in 1962 can be estimated:

$$N = \frac{(600+1)(28827+1)}{(215+1)} = 80,211$$

where

600 is the number of tags applied to yearling males

28827 is the number of 3-year-old males taken from 1 July through 7 August 1964

and

215 is the number of recovered 3-year-old males tagged as yearlings 1 July through 7 August 1964

The estimate seems reasonable, but as previously mentioned, it may be slightly high.

Estimated Pup Population From Sampling Live Pups.--The methods used in marking and in sampling live pups on St. Paul Island in 1964 were the same as those used in 1963 (Roppel, Johnson, and Chapman, 1965), with the following exception. Shearing effort was distributed within each rookery according to the counted distribution of the harem bulls on the rookery. This method gave a more uniform distribution of sheared pups than was obtained in 1963. The number of pups sheared was 27,716.

All the live pups on three rookeries and a separated section of a fourth were counted, and the counts were compared to the estimates obtained on each of the rookeries from sampling (table 21). The estimates for the smaller rookeries were higher than the counts, but the estimate from the larger rookery was slightly less. The total area counted contained 11.0 percent of the total number of harem bulls on both islands. Though desirable, it would be extremely difficult, if not impossible, to count live pups on additional areas.

The estimated pup population for each rookery on St. Paul Island is given in table 22 for two sampling periods. The estimates from pup sampling have been of about the same magnitude since 1961 (table 23). To extend the estimate to include the pup population of both islands, the estimate for St. Paul Island was divided by the usual factor of 0.8, giving an overall estimate of 328,000. This estimate does not include the pups that died prior to shearing, something less than 25,000.

Estimated Pup Population From the Count of Pups on Four Rookeries.--The count of live pups on three rookeries and a portion of a fourth can be used to estimate the total pup population. Assuming that the ratio of pups per harem bull is the same for counted and

Table 21.--A comparison of total pup counts on four rookeries with pup population estimates from marked to unmarked ratios, St. Paul Island, year class 1964

Rookery	Count	Estimated pup population			Percent error in mean of estimates
		8-9 Aug.	15-16 Aug.	Mean	
Kitovi Amphitheatre	1,095	1,522	1,243	1,382	+26
Little Polovina	7,180	8,640	8,130	8,385	+17
Morjovi[1]	17,530	17,300	16,460	16,880	-4
Zapadni Reef	[2]5,700	6,130	6,900	6,515	+14

[1] Rocky Point south of Sea Lion Neck not included.
[2] Count corrected by adding 400 pups estimated to have swum out of the rookery area.

uncounted areas, the total pup population can be estimated from the counted pups and the harem bull count, that is,

$$\frac{31,505}{1,222} : \frac{N}{11,074} ; N = 285,000$$

where

31,505 is the number of pups counted
1,222 is the harem bull count on areas where pups were counted
11,074 is the total count of harem bulls for both islands

and

N is the pup population

The areas where pups were counted contained 11.0 percent of the total number of harem bulls on both islands.

Discussion of the Estimates of the Pup Population.--Recent estimates of the pup population from tag recoveries are lower than those of the mid- and late-1950's. Since 1960, the pup population has also been estimated from marked to unmarked ratios obtained from sampling live pups. The estimate obtained in 1960 was based on samples from only two rookeries; since 1961, all rookeries have been sampled. Where the results of the two methods (tag recoveries and sampling) can be compared, the estimates from sampling are lower than those from tag recoveries (table 24).

Attempts to check the accuracy of the estimates from sampling by counting live pups have been partially effective in that total pup counts were successfully made on one rookery in 1963 and on three rookeries in 1964. From the counts and sampling estimates it is impossible to derive a correction factor that can be used to improve the estimates. A correction factor may not, however, be needed. The counts show that it is highly improbable that the estimated pup population from sampling could be drastically in error. Hence, the best estimate of the 1964 pup population is about 350,000, that is, 328,000 plus pup mortality on land.

Table 22. --Estimates of the pup population from marked to unmarked ratios obtained after shearing, St. Paul Island, year class 1964

Rookery	Seals sheared	First sampling period, 8-9 August			Second sampling period, 15-16 August			Mean of two samples

Seal-pup Weights

Since 1957, seal pups have been weighed annually on St. Paul Island about 1 September. The primary purpose was to determine if the mean weight of pups is related to the return of the year class 3 and 4 years later. There are as yet not enough data to determine if the relation between weight as pups and return of the year class will be of value for predicting returns (table 25). Preliminary studies are not encouraging.

As in previous years (Roppel, Johnson, and Chapman, 1965) the weighing program produced important secondary information on differences in the mean weights of tagged and untagged pups (tables 26 and 27). In 1964, tagged males and females averaged 1.10 and 0.92 kg. less than untagged males and females. This weight difference is 12 percent of the mean weights of untagged males and females.

Appendix table 18 lists the tag numbers and weights of tagged pups by rookery and by sex.

Table 25.--Mean weights[1/] of untagged pups and male returns, Pribilof Islands, Alaska, year classes 1957-60

Year class	Mean weight		Return in thousands
	Males	Females	
	Kg.	Kg.	
1957	8.7 (391)	7.7 (351)	53
1958	11.4 (127)	9.9 (121)	80
1959	9.4 (444)	8.1 (386)	55
1960	9.8 (372)	9.1 (363)	34

RELATED STUDIES

Since 1958, 1,884 skins were collected on St. Paul Island for experimental use in relating economic value to biological factors, particularly age and sex. Table 28 lists the skins taken and marked to permit identification through processing into finished furs.

Table 28.--Skins collected for experimental use, St. Paul Island, 1958 and 1961-64

	Males		Females	
Year	Number	Ages	Number	Ages
1958	-	-	248	2-10
1961	-	-	117	2-5
1962	9	2-4	171	2-15
1963	142	3-6	120	3-6
1964	641	2-7	436	2-6

Experimental skins taken in 1958 and 1961-62 were processed, graded, and sold. Those collected in 1963 and 1964 are currently in cold storage where they will be held until processed.

Sectioned teeth of eight 8-year-old female fur seals were examined by the Laboratory of Radiation Biology, University of Washington. A substance (strontium 90?) which affected photographic film was found in the 1962-63 layer of dentin in certain teeth. Studies are continuing.

A survey was completed of the surface features of sheared sealskin. Plastic impressions were made from the sheared skins of various seals representing the 20 genera of Pinnipedia. One purpose of the study was to provide a key to the identification of fragments found in the stomachs of killer whales, sharks, and other predators.[1,2]

SUMMARY

Males:

1. Of 48,980 male seals killed on the Pribilof Islands in 1964, 47,011 were taken during the male kill from 1 July to 7 August and 1,969 were taken during the female kill 14-28 August. St. Paul Island supplied 37,789, and St. George Island, 11,191. Based on a collection of 6,727 right upper canine teeth, age classification of the kill in percent for ages 2-5 was: St. Paul Island, 7, 60, 28, and 5; St. George Island, 10, 62, 23, and 5. In 1964, male seals were taken from the minimum limits of 42 inches, tip of nose to tip of tail, up to but not including those having a mane.

[1]Victor B. Scheffer. 1964. Hair patterns in seals (Pinnipedia). Journal of Morphology (in press).

[2]Victor B. Scheffer. 1964. Estimating abundance of pelage fibres on fur seal skin. Proceedings of the Zoological Society of London (in press).

2. The peak of the kill occurred during round 7 (27-31 July) when 6,550 males were taken on St. Paul Island. The predicted male kill on St. Paul Island by 5 August 1964 included 24,000 of age 3 and 13,000 of age 4. Actual kills were 22,203 and 10,509 of ages 3 and 4, respectively. The predicted male kill as of 5 August 1964 includes 4,000 of ages 2 and 5, 33,000 of age 3, and 16,000 of age 4.

3. Harem bulls counted 10-17 July 1964 decreased by 2 percent of the 1963 count, and idle bulls were 10 percent less. Counts in 1964 were 11,074 harem and 8,584 idle.

4. Tags and checkmarks recovered from 4-year-old male seals in 1964 yielded an estimate of 614,580 pups of the 1960 year class alive at the time of tagging. Based on tags and checkmarks from 3-year-old male seals, there were 494,724 pups alive at the time of tagging in 1961.

5. Based on tag recoveries at age 3 in 1964 from male seals tagged as yearlings in 1962, an estimated 80,211 male seals of the 1961 year class survived to age 1.

6. Exclusive of pups that died before shearing, marked to unmarked ratios obtained from shearing the heads of 27,716 pups and subsequent sampling yielded an estimate of 353,000 pups born on the Pribilof Islands in 1964. Total counts of live pups on three rookeries and a portion of a fourth supported the estimates.

Females:

1. Of 16,452 female seals killed on the Pribilof Islands in 1964, 14,602 were taken during the female kill 14-28 August and 1,850 were taken during the male kill from 1 July to 7 August. Seventy-two percent were in ages 2-5, and 28 percent were age 6 and older. Age classification of the kill was based on a collection of 3,034 right upper canine teeth. Females having black or a mixture of black and white vibrissae were selected for killing; most females having white vibrissae were allowed to escape.

2. There was little difference in the age composition of females taken from traditional male hauling grounds, from rookery fringes, or from mixed areas.

3. Of 147 3-year-old females examined, none had given birth to pups in 1964 or previously. Three of 73 4-year-old females were primiparous and post partum.

4. Pup populations estimated from tags and checkmarks recovered from females were 604,546 for the 1960 year class at the time of tagging and 473,131 for 1961.

Tag Recoveries and Tagging:

1. The kill in 1964 included 4,205 seals tagged as pups and 1,890 with checkmarks only. In addition, 45 Soviet-tagged seals were taken, and 302 seals selected and tagged as yearlings in previous years were recovered.

2. A total of 24,991 pups were tagged on the right fore flipper with Q-series tags. The tip of the same flipper was sliced off as a checkmark.

3. Three counts of yearlings tagged as pups in 1963 were made from 24 September to 8 October on nine sample areas on St. Paul Island. The counts may make possible an index to survival from birth to age 1 and assist in predicting the return of 3-year-old male seals 2 years later.

Mortality: Pup mortality on land decreased to 25,042 in 1964 from 39,239 in 1963. The 1964 level was the lowest recorded since the beginning of complete dead-pup counts in 1953.

Seal-pup Weights: Weights of 1,191 pups showed that tagged males and females weighed 1.10 and 0.92 kg. less than untagged males and females.

ACKNOWLEDGMENTS

The research staff appreciates the cooperation given them by C. Howard Baltzo, Program Director; Howard Euneau, St. Paul Island Manager; Roy D. Hurd, St. George Island Manager; Bertel W. Johnson, Management Staff Officer; and Richard A. Hajny, Wildlife Management Biologist, Pribilof Islands.

GLOSSARY

The following terms used in fur seal research and management on the Pribilof Islands have special meanings or are not readily found in standard dictionaries.

Age Class Age group. Seals of the same age (usually used when referring to seals older than pups). See year class.

At Time of Tagging (or Sampling) Phrases used to qualify estimates of the population based on (1) tag returns at various ages or (2) sampling for a marked to unmarked ratio in the summer of birth. In either case, an estimate of the total number of pups born in a given year would include pups alive "at time of tagging" ("or sampling") plus the number that died before tagging or sampling.

Checkmark A notch, slit, hole, or other mark made on a seal flipper when a tag is applied, to insure later recognition of an animal which has lost its tag.

Clinch or Clinching The device or action by which metal tags applied to seal flippers are fastened. A metal point is inserted through an opening in the opposite end of the metal strip then bent over a narrow band to form a closed ring (or tag).

Drive The act of surrounding and moving groups of seals on land from one location to another.

Escapement Seals that were not killed because they were either too old, too large, or were not available.

Female Kill That part of the annual harvest devoted principally to the kill of female seals, usually in August. See male kill.

General Breeding Season Organized breeding beginning about mid-June and ending in early August. Identifiable by the formation of harems. A limited amount of breeding also occurs after the break-up of the harem structure.

Hauling Grounds An area, usually near a rookery, on which nonbreeding animals congregate.

Haul Out The act of seals moving from the sea to a rookery or hauling grounds on shore.

Homing Tendency The inclination of seals to return to the rookery where they were born, that is, home rookery or rookery of birth. Homing tendency is expressed as a percentage by comparing the number of tagged seals in a specific group that were found on their natal rookery with the number that were found on some other rookery or island.

Known-Age Applied to seals for which age is definitely known because they bear an inscribed tag or have a certain combination of tag scar and checkmark.

Male Kill That part of the annual harvest devoted principally to the kill of male seals, usually in late June, in July, and in early August. See female kill.

Marked Seals that have been tagged, sheared, or otherwise artificially marked so that they can be identified.

Marked to Unmarked Ratio The number of marked seals compared to the number of unmarked seals, usually expressed as a decimal fraction. Example, 5:20, ratio .25.

Mixed Areas Areas behind some of the rookeries on which few seals appear until August, or after the general breeding season. Seals using these areas at that time may be a mixture of animals from traditional hauling grounds and from the rookery.

Mortality Rate Percent of a year class dying during a specific period.

Pregnancy Rate Percent females that were carrying or had borne pups in the year examined. For example, the pregnancy rate of 5-year-old females was 69 percent.

Return The return or survival of seals from a year class. For example, 10,000 3-year-old seals from the 1960 year class returned in 1963.

Round The sequence in which hauling grounds on St. Paul Island are visited in order to collect seals for harvest. Current practice is to make a complete circuit or round of the hauling grounds in 5 days, repeating the procedure throughout the male kill. The round system is not followed during the female kill on St. Paul Island, nor during the male and female kills on St. George Island.

Round-Up The act of surrounding and collecting seals to be driven for harvest, tagging, or other purposes.

Tagged Describes a seal having an inscribed metal tag or tags attached to one or more of its flippers.

Tag-Lost A term applied to a seal that is known to have been tagged because of a checkmark and, in some cases, a healed tag scar. See tag scar.

Tag Scar A hole or torn area near the usual tag site on a seal's flipper. Tags fall out because of poor clinching or wear and are forcibly torn out by catching in rock crevices or driftwood. Possibly some are torn out by the tagged seal.

Tagged to Untagged Ratio See marked to unmarked ratio.

Tag Lost to Tag Ratio The number of seals that have lost tags as compared with the number retaining tags. Usually expressed as a decimal fraction.

Year Class Group of seals born in the same year. See age class.

Appendix A

PREDICTION OF 1965 MALE KILL

Douglas G. Chapman

16 November 1964

Quantitative methods of predicting the annual male fur seal harvest were first discussed in 1959.[1] This discussion was concerned both with preseason and inseason predictions. Subsequently, only preseason predictions were studied and actually made for the seasons 1961 to 1964. Several methods were used in this prediction analysis. The predictions for most years were only moderately successful, though the forecast for 1964 was the most accurate yet made. Nevertheless, the prediction errors still are quite large. Some attempt is made to assess these errors, but this is difficult because each prediction may be a composite of several partially independent predictions. Moreover, various "adjustments" have to be made in previous data for varying termination dates of the kill and length limits, and additional adjustments must be made in the predictions to extrapolate St. Paul Island estimates to both islands.

As is obvious, the forecast of the 4-year male kill is relatively easy, since the kill of the 3-year-olds from this year class provides a substantial amount of data on which to base the forecast. The prediction of the larger 3-year-old component is based on much more tenuous data; thus the errors of prediction for a kill of this age class are much larger.

Prediction of 4-year old male kill

Predictions of 4-year-old male kills in former years have been based on one or more of (a) the estimate of 3-year male escapement, (b) the population-return equation, (c) the dead-pup count-return equation, and (d) the temperature-return equation.

Chapman (1964) showed that the estimates of escapement based on estimating the return of 3-year males after termination of killing and the proportion of undersize or oversize animals were inconsistent with the estimates of recruitment to the population of adult males. Consequently, the escapement estimate was replaced by a direct regression of 4-year male kill on 3-year male kill and the mean date of the latter.

An analysis made in 1963 (appendix table 3; Roppel, Johnson, and Chapman, 1965) showed that the dead-pup count yielded essentially no additional predictive information over the temperature data, and thus this regression was also eliminated.

New data available in 1964 may be useful for forecasting purposes, that is, the recovery of seals selected and tagged as yearlings in 1962. This provides an estimate of the size of the 1961 year class in 1962 when it is hoped that the heaviest and most variable component of mortality has already taken place. If this is true, a small proportion can be subtracted from this estimated number of yearlings for mortality in the next 2 years, and the balance will then either be harvested or escape to join the breeding reserve.

Method 1.--Regression of 4-year-male kill on 3-year-male kill and the mean date of the kill of 3-year-olds. This regression is based on the data in appendix table 1.

Because there were two starting dates and several termination dates for the kills during the past several years, the adjustments indicated in the footnotes to appendix table 1 were made. The basis of these adjustments was reported previously (Roppel, Johnson, and Chapman, 1965).

Appendix table 1.--The 3- and 4-year-old male kill and mean date of the 3-year-old male kill, St. Paul Island, year classes 1952-60

Year class	3-year male kill to 31 July	4-year male kill adjusted[1]	Mean date of 3-year male kill[2]
	Number	Number	Days after 15 July
1952	31,000	29,000	5
1953	27,000	17,000	4
1954	17,000	11,000	3
1955	27,000	11,000	2
1956	10,000	3,000	3
1957	15,000	20,000	4
1958	30,000	27,000	4
1959	20,000	17,000	3
1960	12,000	12,000	4

[1] Kill of 4-year-old males to 31 July, plus 80 percent of the number of 3-year-old males taken after 31 July from the same year class.

[2] Adjusted to the base of a common starting round on 27 June.

[1] Douglas G. Chapman [p. 49]. In Carl E. Abegglen, Alton Y. Roppel, and Ford Wilke. Alaska fur seal investigations, Pribilof Islands, Alaska. Report of Field activities, June-September 1959. Bureau of Commercial Fisheries Marine Mammal Biological Laboratory, Seattle, Wash. [Processed.]

The regression determined from the data is:

$$Y = -15.10 + 0.60\,x_1 + 5.29\,x_2$$

where x_1 = kill of 3-year-old males to 31 July

x_2 = mean date of the 3-year-old male kill in days past 15 July

Y = kill of 4-year-old males to 31 July, plus 80 percent of the 3-year-old male kill after 31 July

This regression, which is based on 1 year of additional data, is very similar to that given in 1963 (Roppel, Johnson, and Chapman, 1965), and to two decimals, R^2 is 0.82 as it was in 1963.

For the 1961 year class, which will be 4 years old in 1965, $x_1 = 18$, $x_2 = 4$, so that $Y = 16.9$.

Deleting 3,900 (80 percent of the 3-year male kill of 1964 after 31 July) and adding 10 percent for the 4-year male kill expected in August 1965, yields an estimate of 14,300 for the 1965 4-year-old male kill.

Method 2.--Temperature-return regression. The basic data for this regression are given in appendix table 2.

The regression is:

$$Y = 16.0 + 0.99\,T$$

where Y = adjusted kill

T = mean temperature in tenths of a degree above 32°

Appendix table 2.--The 3- and 4-year-old male kill and mean temperature, St. Paul Island, year classes 1950-60

Year class	Adjusted kill[1]	Temperature[2]
	Number	Degrees Fahrenheit
1950	56,000	35
1951	50,000	36
1952	60,000	37
1953	44,000	16
1954	28,000	10
1955	38,000	17
1956	13,000	1
1957	35,000	23
1958	57,000	34
1959	37,000	33
1960	23,000	26

[1] Kill prior to 31 July, plus 80 percent of the number of 3-year-olds taken in August.

[2] Mean temperature for 12-month period ending 30 June of the indicated year, measured in tenths of a degree above 32°.

For 1961, the value of T is 18, so that Y = 33.8. The kill of 3-year-old males in 1964 prior to 31 July was 17,600, and 80 percent of the kill in August (4,861) is 3,900, so that there remains for 1965 (to 31 July), 12,300. An additional 10 percent expected in August 1965 brings the total kill of 4-year-old males to 13,500.

Method 3.--Estimates from the yearling population estimate. Of 621 male yearlings tagged or retagged in 1962, 259 were recovered in 1963 as 2-year-olds or in 1964 as 3-year-olds. Additionally, in 1963 and 1964, nine were recovered as 3- and 4-year-olds, respectively, indicating a small degree of error in the estimating of ages during tagging. These nine seals were the survivors of 2 years' natural mortality at a rate of approximately 10 percent per year. Also, the 3-year-old kill is approximately equal to the 4-year-old kill plus escapement, so that it may be estimated that these 9 suggest that a total of 20 of the original 621 were older than 1 at the time of tagging. The total 2-year-old kill on both islands in 1963 was 2,019, and the 3-year-old kill in 1964 totaled 29,416. Combined, these kills total 31,435. Hence, the estimate of the number (N) of yearlings from both islands alive in 1962 is:

$$N_{1962} = \frac{(31,436)(602)}{260} = 72,786 \text{ or } 72,800$$

Reducing 72,800 by 10 percent for the annual mortality from age 1 to age 2 (a very rough estimate) and the 2-year-old kill, and further reducing it by 10 percent for the next year's natural mortality and a kill of 29,400, leaves a balance of 27,800. A further overwintering mortality in 1964-65 of 10 percent and an escapement of about 10,000 imply a balance of 15,000 for the 4-year-old male kill in 1965. Eighty percent of this is 12,000, which would be the St. Paul Island estimate by this method. Despite the obvious inadequacies of the data used in this method, it agrees very closely with the previous two estimates.

Prediction of 3-year-old Male Kill

In the past several years, the prediction of the 3-year-old male kill has been based on one or more of (a) the population-return equation, (b) the dead-pup count-return equation, and (c) the temperature-return equation. In addition, attempts have been made to utilize the 2-year-old male kill data on the cumulative estimates of the female population for forecast purposes. These have been unsuccessful, though some additional discussion on the cumulative estimate and its relationship to the 3-year-old kill is given below. Also, a forecast based on the return from yearling tagging is obtained.

Method 1.--Temperature-return regression. This forecast equation, which was given on page 27, implies a return of 36,800 for the 1962 year class (for which T = 21). This return, or adjusted kill, is the kill of 3- and 4-year-old males to 31 July, plus 80 percent of the kill of 3-year-old males in August. Where the termination date has been 5 August, the total 3- and 4-year-old male kill has exceeded this adjusted kill by about 8 percent.

Hence, this suggests a kill from the 1962 year class at ages 3 and 4 of 39,700. In years with a 5 August termination date, the 3-year-old male kill is about 61 percent of the total 3- and 4-year-old male kill. This leads to an estimated St. Paul Island 3-year-old male kill in 1965 of 24,000.

Method 2.--Yearling estimate. In 1963, 551 yearling males were tagged or retagged. In 1964, 56 recoveries were made of these males that were of the correct age, that is, 2 years old. In addition, there were three of age 3, that is, animals that were age 2 at the time of tagging. The proportion older than 1 at the time of tagging is similar to the situation in the previous year, that is, from the 1962 yearling tagging 44 2-year-old males and 2 3-year-old males were recaptured in 1963. The subsequent data have shown that the proportion older than 1 in 1962 was 3.2 percent. Using this adjustment, the estimated size of the yearling class in 1963 was:

$$N_{1963} = \frac{3,679(534)}{57} = 34,500$$

Here 3,679 = 3,678 + 1, where 3,678 is the 1964 2-year-old male kill. This is obviously a low estimate. The estimate made on the basis of similar data in 1963 of the size of the yearling class in 1962 was similarly low. It was in fact:

$$N^1_{1962} = \frac{(2,020)(606)}{45} = 27,200$$

This suggests that the 1963 yearling group may have been 27 percent larger than the 1962 yearling group ($\frac{34.5}{27.2} = 1.27$).

With other mortality factors remaining about the same, this implies a St. Paul Island 1965 3-year-old male kill of (24,500)(1.27) or 28,600.

Other methods.--A complete kill of all available 2-year-old males in late July would seem to be a possible index of the later harvest to be expected from a year class. To obtain uniform data over a period of years, a regression of the 3-year-old male kill to 31 July was calculated on the kill of 2-year-old males in the last round (27-31) of July of the previous year, that is, from the same year class. The regression is Y = 14.9 + 1.713X, which is based on data from the 1952-61 year classes. Here Y is the 3-year-old male kill (in thousands) to 31 July, and X is the kill (in hundreds) of the 2-year-old males in the last round (27-31) of July of the previous year. For the 1962 year class, X = 4.3, hence Y is predicted to be 21.9. Adding 10 percent for the expected kill in August yields a season total of 24,100. This is in excellent agreement with estimates found by methods 1 and 2. The value of r^2 for this relationship, however, is only 0.20, that is, only 20 percent of the variation of Y is associated with or due to X. Thus the relationship can be expected to yield quite erratic predictions in general.

As mentioned earlier, an estimate of the predicted 3-year-old male kill for 1964 was based, in 1963, on the ratio of past kills to the cumulative female population estimate. Though this was unsatisfactory, it was thought that the cumulative female estimates might be used with the temperature data to give improved estimates. The cumulative estimates taken from a previous study (Chapman, 1964) are given in appendix table 3.

Appendix table 3.--Cumulative female population estimates, 1950-60

Year	Estimate	Year	Estimate
1950	850,000	1956	860,000
1951	850,000	1957	800,000
1952	830,000	1958	740,000
1953	840,000	1959	650,000
1954	850,000	1960	610,000
1955	870,000		

A regression of the adjusted kill, as shown in appendix table 2, was calculated using these estimates and temperature data (also given in appendix table 2). The resulting equation is:

$$Y = -56.0 + 1.20\,T + 0.84F$$

where Y = adjusted kill

T = temperature (in tenths of a degree above 32)

F = estimated number of females

The addition of the new variable is significant when tested by the usual analysis of variance methods (F = 12.08, which is highly significant) and for the multiple regression $R^2 = 0.85$, which is very high. When applied to the data for 1961, however, the estimated Y is 17,800, which is lower than the number of 3-year-old males already taken in 1964. Whether this is an aberrant observation or whether the relationship is already changing as the herd responds to the reduction program that has taken place must be left for future observations to decide.

Reliability of the Estimates

For the estimates obtained directly from a regression equation it is easy to compute confidence interval estimates to suggest their reliability. Final estimates, however, are obtained by additional adjustment which add additional variability. On the other hand, the agreement between estimates obtained in different ways yields additional confidence.

Some confidence intervals are:

For the estimate of the 4-year-old male kill to 31 July by method 1, Y lies between 16,900 $\pm$ 10,500, that is, between 6,400 and 27,400 with 95 percent confidence.

For the estimate of the adjusted kill of the 1961 year class by method 2, the 95 percent confidence interval for Y is 33,800 $\pm$ 23,000, that is, from 10,800 to 56,800.

The width of these confidence intervals should indicate the caution that must still be exercised in regard to forecasts of the male harvest.

Final Predictions by Ages and by Islands

The estimates given above are averaged to yield St. Paul Island figures. Further, the long-term relation between St. Paul and St. George Island in regard to the male kill is the basis of the extrapolation of the estimate to St. George Island. It should be pointed out, however, that in 1964 as in 1963 the fraction of the kill on St. George Island was higher than the long-term average. The average of the St. George Island kill to the total for both islands for the period 1950-64 is exactly 20 percent. The results are shown in appendix table 4.

Appendix table 4.--Prediction of the kill in 1965, by age, Pribilof Islands, Alaska

Island	Age			Total
	2 and 5	3	4	
St. Paul	3,000	26,000	13,000	42,000
St. George	1,000	7,000	3,000	11,000
Total	4,000	33,000	16,000	53,000

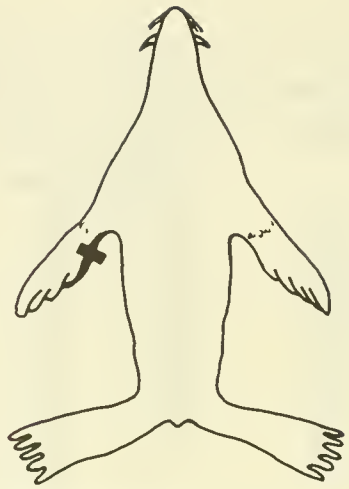
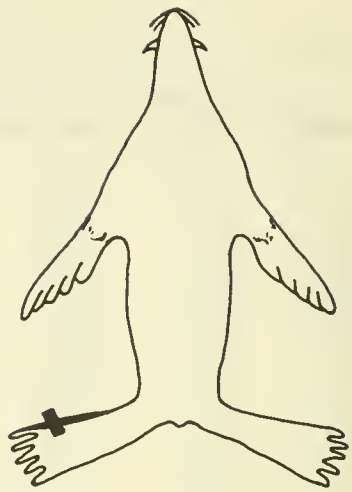
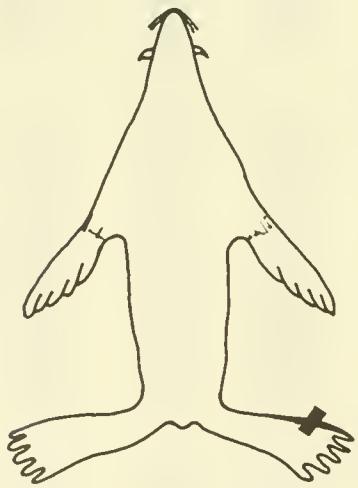
Series: A - 1947
Tag location: left front flipper
Check mark: 1/4" hole in hind left flipper
Number tagged: 19183



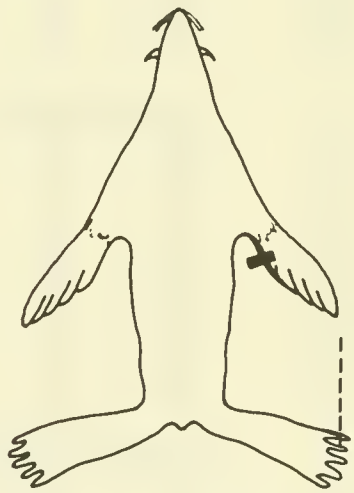
Series: B - 1948
Tag location: left front flipper
Check mark: none
Number tagged: 19532



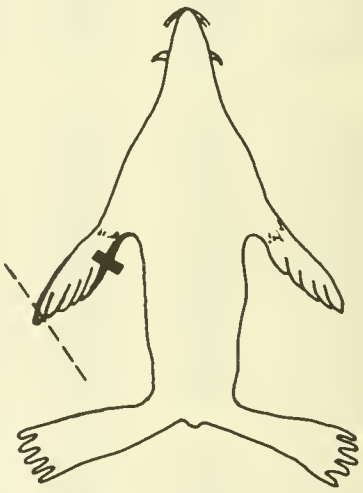
Series: CS - 1949
Tag location: left hind flipper
Check mark: none
Number tagged: 19960



Series: D - 1951
Tag location: right hind flipper
Check mark: none
Number tagged: 1000

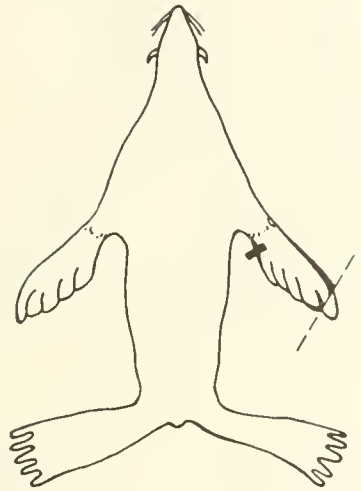


Series: E - 1952
Tag location: right front flipper
Check mark: tip of digit on right hind flipper sliced off
Number tagged: 19979

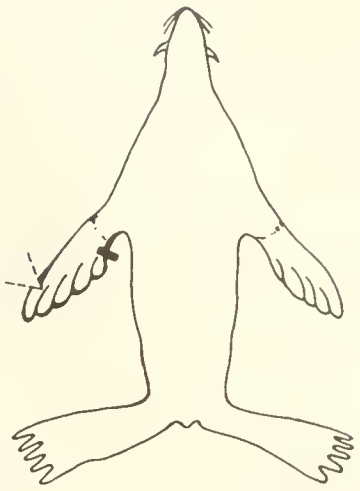


Series: F - 1953
Tag location: left front flipper
Check mark: tip of left front flipper sliced off
Number tagged: 10388
G - 1953 70001-7400

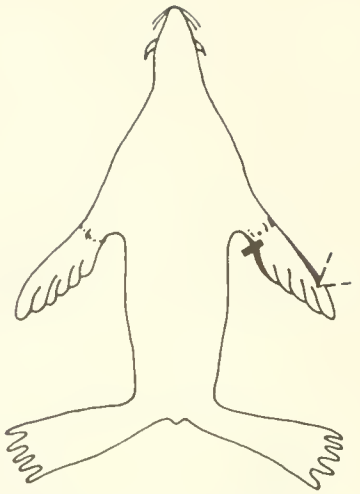
Appendix figure 1.--Tag and checkmark locations, fur seal pup tagging, Pribilof Islands, Alaska, 1947-64.



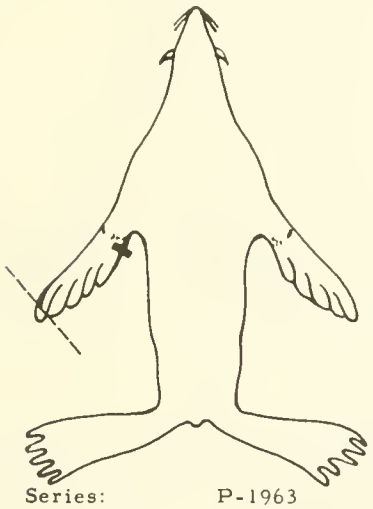
Series: M - 1960
Tag location: right front flipper
Checkmark: tip of right front flipper sliced off
Number tagged: 59981



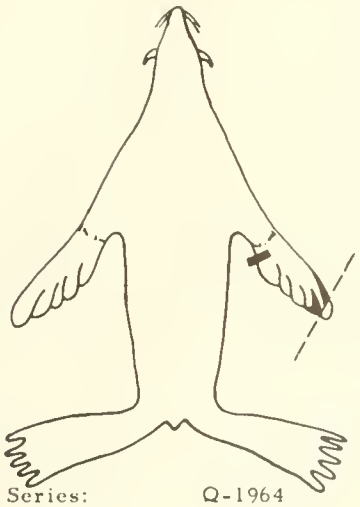
Series: N - 1961
Tag location: left front flipper
Checkmark: "V" notch on left front flipper
Number tagged: 49921



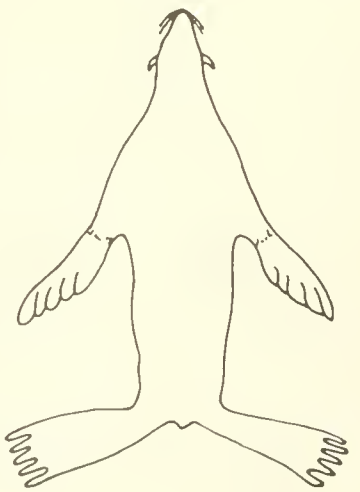
Series: O - 1962
Tag location: right front flipper
Checkmark: "V" notch on right front flipper
Number tagged: 49,908



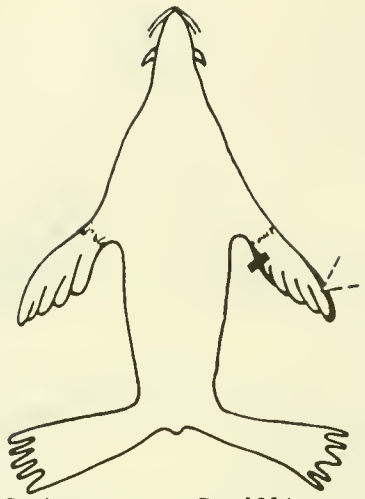
Series: P-1963
Tag location: left front flipper
Checkmark: tip of left front flipper sliced off
Number tagged: 24, 971



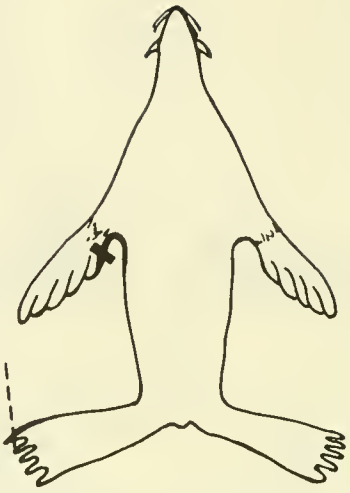
Series: Q-1964
Tag location: right front flipper
Checkmark: tip of right front flipper sliced off
Number tagged: 24, 991



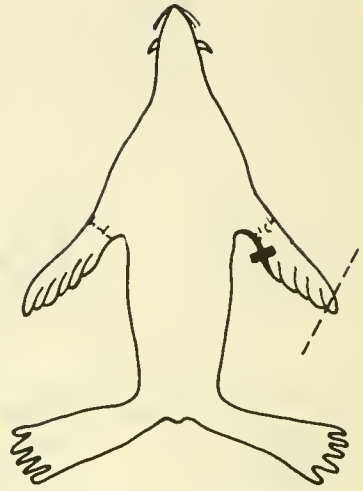
Appendix figure 1.--Tag and checkmark locations, fur seal pup tagging, Pribilof Islands, Alaska, 1947-64.--Continued



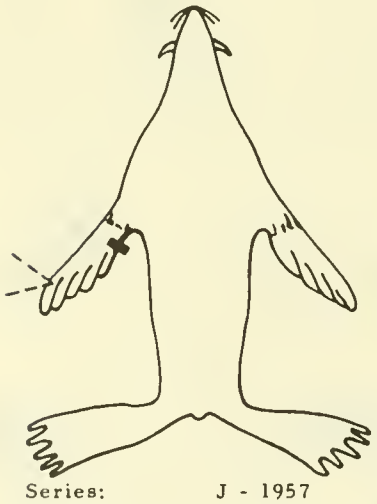
Series: G - 1954
Tag location: right front flipper
Check mark: "V" notch on right front flipper
Number tagged: 10000



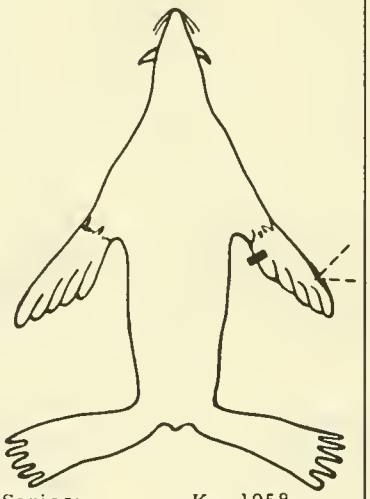
Series: H - 1955
Tag location: left front flipper
Check mark: tip of digit on left hand flipper sliced off
Number tagged: 49870 No letter
H-1955 1-10000 10001-50000



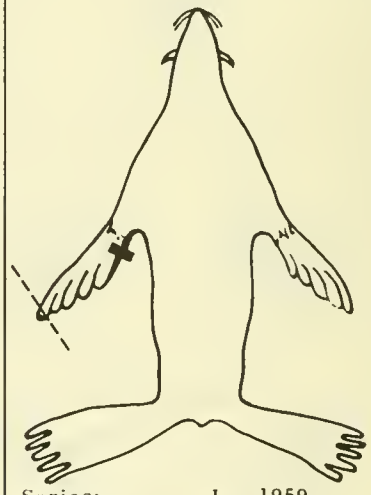
Series: I - 1956
Tag location: right front flipper
Check mark: tip of right front flipper sliced off
Number tagged: 49794



Series: J - 1957
Tag location: left front flipper
Check mark: "V" notch on left front flipper
Number tagged: 49842



Series: K - 1958
Tag location: right front flipper
Check mark: "V" notch on right front flipper
Number tagged: 49917



Series: L - 1959
Tag location: left front flipper
Check mark: tip of left front flipper sliced off
Number tagged: 49881

Appendix figure 1.--Tag and checkmark locations, fur seal pup tagging, Pribilof Islands, Alaska, 1947-64.--Continued

Created in 1849 the Department of the Interior--a department of conservation--is concerned with the management, conservation, and development of the Nation's water, fish, wildlife, mineral, forest, and park and recreational resources. It also has major responsibilities for Indian and Territorial affairs.

As the Nation's principal conservation agency, the Department works to assure that nonrenewable resources are developed and used wisely, that park and recreational resources are conserved for the future, and that renewable resources make their full contribution to the progress, prosperity, and security of the United States--now and in the future.
