ABSTRACT

This report describes the oceanographic methods used, and lists in tabular form the results obtained, on Expedition SCOT in the eastern tropical Pacific. This expedition, conducted in April, May and June, 1958, by the Scripps Institution of Oceanography with the co-operation of the Inter-American Tropical Tuna Commission, was the first of a series of cruises devoted to the oceanography of the United States tropical tuna fishing region. These cruises are part of a program of investigations carried out by the Scripps Institution under contract to the U. S. Bureau of Commercial Fisheries.

The main object of the expedition was to study the distribution of ocean properties in the region as a whole at a different season and with greater coverage than in any former expedition. The survey extended from San Diego, California, to latitude 5°N.

Properties measured or computed were: weather conditions, temperature, salinity, density, thermosteric anomaly, dynamic height anomaly, dissolved oxygen concentration, inorganic phosphorus concentration, the attenuation of diffuse submarine daylight, incident solar radiation, chlorophyll a, standing crop of zooplankton, standing crop of small nekton, surface current direction and velocity (by GEK), and primary production rate. Additional information presented includes a summary listing of bathythermograph observations and of organisms captured in night-lighting operations. Some preliminary results of analysis of data, including experiments made aboard ship on the growth of ocean phytoplankton in response to various combinations of added chemicals, are given.

**PHYSICAL, CHEMICAL, AND BIOLOGICAL OBSERVATIONS
IN THE EASTERN TROPICAL PACIFIC OCEAN
SCOT EXPEDITION, APRIL-JUNE 1958**

SCOT (Scripps Cooperative Oceanography and Tuna) Expedition, carried out between 23 April and 20 June 1958, in eastern tropical Pacific waters, was a cooperative venture utilizing funds and personnel of the Scripps Institution of Oceanography (Tuna Oceanography Research Project) and the Inter-American Tropical Tuna Commission. The reference number of the cruise for Scripps Institution purposes is TO-58-1. Funds for the Scripps Institution group were provided by the U. S. Bureau of Commercial Fisheries under Department of Interior Contract 14-19-008-9354. The Scripps research vessel Spencer F. Baird, Captain A. W. Phinney commanding, was employed. The main objectives of the expedition were:

- a. to augment our knowledge of the seasonal and regional variations in primary production and standing crops of phytoplankton, zooplankton, and nekton, and their relationships to tuna abundance and to the physicochemical environment in areas of interest to the American tuna fisheries;
- b. to study the abundance and distribution of tuna eggs and larvae in waters west of the Mexican mainland north of 17°N latitude;
- c. to study the physical, chemical, and biological features common to oceanic "fronts" in the vicinity of southern Baja California.

The Scripps Tuna Oceanography Research (STOR) group was primarily concerned with objective (a). The expedition data, together with similar information gathered on previous and subsequent investigations will provide the basis for an evaluation of the biological events in the ocean environment with special reference to the distribution and behavior of tunas.

Objectives (b) and (c) were of particular interest to scientists of the Inter-American Tropical Tuna Commission since such work forms an integral part of their continuing field research program.

It was originally intended that the latter portion of the expedition (Acapulco-San Diego) would be carried out under the leadership of Dr. Bell M. Shimada of the Inter-American Tropical Tuna Commission, and devoted mainly to the Commission's objectives. Unfortunately, the death of Dr. Shimada and his colleague,

Mr. Townsend Cronwell, en route to join the expedition, prevented the complete fulfillment of these objectives. Objective (c) was abandoned. Dr. Maurice Blackburn, STOR Project Leader, took charge of the work and attained objective (b) before returning to San Diego.

Figure 1 shows the expedition track.

The following is a list of scientific personnel who participated in the expedition:

**Mr. Carl M. Boyd, Research Assistant, Scripps Institution

Dr. Maurice Blackburn, Associate Research Biologist, Scripps Institution (Expedition Leader, Acapulco-San Diego)

*Mr. Donald E. Hollingshead, Laboratory Technician, Scripps Institution

*Mr. Robert W. Holmes, Assistant Research Biologist, Scripps Institution (Expedition Leader, San Diego-Acapulco)

Mr. Witold L. Klawe, Scientist, Tuna Commission
Mr. John M. Jaynes, Marine Technician, Scripps Institution

Mr. Robert J. Linn, Senior Marine Technician, Scripps Institution

Mr. A. Dougall Reith, Senior Marine Technician, Scripps Institution

*Mr. Alan C. Smith, Marine Technician, Tuna Commission

Mr. Paul N. Sund, Scientist, Tuna Commission

*Dr. William H. Thomas, Assistant Research Biologist, Scripps Institution

* San Diego-Acapulco

** Acapulco-San Diego

SUMMARY OF PRELIMINARY RESULTS

While most of the data obtained on SCOT have not yet been examined in detail, certain of the biological relationships have been examined cursorily and are presented below to illustrate some of the types of relationships that are being examined. More detailed and rigorous expositions will appear elsewhere.

Interrelationships of Standing Crops - Phytoplankton, Zooplankton, and Nekton (R. W. Holmes and M. Blackburn)

In figure 2 surface chlorophyll a concentration is

Figure 1. Track of SCOT Expedition showing noon stations.

Figure 2. Surface chlorophyll a -zooplankton volume (small organisms) relationship for EASTROPIC, SCOPE, and SCOT.

presented as a function of zooplankton volume for data obtained on SCOT, SCOPE, and EASTROPIC expeditions. The SCOT data increase the significance of the relationships previously observed (SCOPE and EASTROPIC) and show that seasonal variations do not alter the relationship. The water-column chlorophyll *a* (mg/m^2) and zooplankton-volume relationship is presented in figure 3. Again a significant relationship is obtained and the coefficient of variation is nearly identical in the two cases. These data strengthen our previous belief that the zooplankton is autochthonous and that seasonal variations in the relationship are quite small.

Figure 4 is a plot of zooplankton volume against nekton volumes obtained at night stations on SCOT Expedition. The zooplankton data, like those in figures 2 and 3, refer to standard oblique meter net hauls with 450 m of wire out and are made available by courtesy of the Inter-American Tropical Tuna Commission. The nekton volumes refer to standard hauls. This relationship is statistically significant. It may be concluded from figures 2-4, for the general area and season covered by SCOT, that:

1. The biological events leading to the production of a particular crop of nekton (tuna food) occur in the same locality as the crop itself, and
2. The standing crops at the lower trophic levels are replaced about as fast as they are grazed down by those above.

Zooplankton Standing Crops Around Islands
(M. Blackburn)

Observations made on SCOT Expedition around Clarion, Clipperton, and Cocos Islands, with the help of Messrs. Klawe and Sund of the Inter-American Tropical Tuna Commission, form a small but interesting addition to the study of zooplankton standing crop gradients around ocean islands. Stations were occupied on opposite sides of each island at a distance of about 11 miles from it and a third station was occupied at a distance of about half a mile from the island; each set of stations was occupied in the daylight and again at night. Catches made in oblique hauls of nets are not altogether comparable because the inshore hauls had to be made at shallower depths, but catches from surface horizontal tows, which show similar trends, are comparable. The results of surface tows, in displacement volumes ($\text{ml}/1000\text{m}^3$), may be summarized as follows;

arrowheads indicate apparent gradients of increasing crop away from the island (Clarion) or towards it (Clipperton, Cocos).

CLARION ISLAND

Day	12	←	4	→	10
Night	37	←	19	→	36

CLIPPERTON ISLAND

Night	173	→	188	←	55

COCOS ISLAND

Day	58	→	152	←	70
Night	138	→	210	←	95

Oceanographic Survey of Gulf of Tehuantepec
(M. Blackburn)

The period May 27 - June 2 of SCOT Expedition was devoted to a survey of the Gulf of Tehuantepec in southern Mexico, an area in which yellowfin tuna aggregate in winter and spring. This area has been selected for intensive study, by means of cruises and moored stations, over a one-year period; the only previous organized oceanographic work was for a few days in December 1955, during EASTROPIC Expedition. It is frequently disturbed by offshore (trans-isthmian) winds during the fishing season, which suggests both the feasibility and the practical need of some system of forecasting tuna distribution from wind conditions. Other interesting features of the area are that it is in the warmest part of the eastern Pacific and a poor area for skipjack tuna.

The Eastropic observations indicated the presence of a thermal dome, with thermocline top at 10 m below the surface at about $15^{\circ}10'N$, $95^{\circ}30'W$. The SCOT hydrocast and BT data revealed the presence of a thermal ridge with axis along $95^{\circ}W$ between about $14^{\circ}30'$ and $15^{\circ}50'N$, with thermocline top at about 20 m. To the west of the ridge the thermocline fell sharply by some 50 m into a hollow at about $96^{\circ}30'$, beyond which it rose in a rather ill-defined way. Isoleths of salinity, thermocline anomaly, oxygen, and inorganic phosphorus showed the same trends as the isotherms. Surface temperatures, which over much

Figure 3. Water column chlorophyll *a*-zooplankton volume (small organisms) relationship for SCOPE and SCOT.

Figure 4. Regression of nekton volume, including jellies, standardized to a haul time of 65 minutes, on zooplankton volume (small organisms).

of the Gulf were between 30° and 31°C, were below 28°C at the top of the thermal ridge, where surface phosphorus concentrations were also higher than to the east or west. Surface circulation measured by GEK was in good agreement with that indicated by the dynamic topography, especially between the above-mentioned ridge and hollow where it was of the order of 1 to 2 kt in a southwesterly direction. The distribution of zooplankton standing crop was what might be expected if a crop recently produced on the ridge were in process of transportation downcurrent.

The area is to be resurveyed further.

Experimental Assessment of Phytoplankton-limiting Nutrients and the Culturing of Pelagic Phytoplankton
(W. H. Thomas)

At SCOT Stations 4 and 49 (figure 1) 5-gallon water samples were taken at a depth of 10 m. Station 4 was located in the oligotrophic area west of Baja California and Station 49 was located in the eutrophic "Dome" area off Central America. Fifty-ml aliquots of these samples were dispensed into forty-two 125-ml flasks to which suspected nutrients were added in various combinations. Fourteen such treatments were set up in triplicate. The nutrients used were N, P, Si, trace elements, soil extract, purines and pyrimidines, and amino acids. After addition of nutrients the flasks were incubated at 25°C and were illuminated continuously at 600-900 foot-candles. The response of the phytoplankton in each flask was estimated at daily intervals by examination with the naked eye and by microscopic examination. The latter task proved quite feasible in the calm weather experienced. A millipore filter slide was made initially to determine which phytoplankton genera were the dominants in the original sample.

One of the purposes of these experiments was to determine which nutrients might be limiting in these waters. If the response to a given single nutrient was greater than the response to any other, then presumably the former would be the more likely limiting nutrient. If, when a given nutrient was omitted from a complete mixture and the response was less than in the complete mixture, then the omitted nutrient might be limiting. Another purpose of these experiments was the establishment of cultures of truly pelagic phytoplankton which could be used for photosynthesis and nutritional studies.

The first experiment (Station 4) was started on

April 26, 1958. Approximately 500 cells per liter were found in the original water. The following genera were observed on the Millipore slide: Navicula, Ditylum, Coscinodiscus, Ceratium, Dinophysis, Gonyaulax, Peridinium. A small unidentified pennate diatom was the most prevalent organism seen, however. None of these organisms grew in any treatment. After 3 days cultures containing the complete supplement (N, P, Si, trace elements, soil extract) plus purines, pyrimidines, and amino acids, were visibly turbid owing to intense bacterial growth. After 5 days very small green flagellates were seen in these cultures. These organisms were also observed after 6 days in cultures containing the complete supplement without purines, pyrimidines, or amino acids. They also developed in the treatment in which phosphate was omitted from the complete supplement. Nothing developed in the other 10 treatments containing no additions or nutrients added singly, or when N, Si, trace elements, or soil extract were respectively omitted from the complete mixture. Since none of the more prevalent organisms seen in the original sample grew, the experiment did not show what factors might be limiting the major portion of the phytoplankton. The small flagellate was transferred to fresh complete medium and persisted through several subcultures.

The second experiment was started on May 13, 1958. Five hundred thousand cells per liter were found in the original water sample, which was visibly green. The dominant genera were Nitzschia, Rhizosolenia, and Chaetoceros. Other diatoms seen on the Millipore slide were Navicula and Planktoniella. About 10-20 percent of the population consisted of dinoflagellates of the genera Gymnodinium and Peridinium. Ceratium and Gonyaulax were also seen in net hauls.

The results of this experiment are shown in table 1.

No growth occurred in the second experiment when nothing was added or when nutritional factors were added singly, with the exceptions of the treatment in which soil extract was added alone and possibly in the trace element treatment. Growth occurred in all the combination type treatments, but no diatoms developed in cultures containing no added Si, trace elements, or soil extract. Since diatoms did grow in cultures containing no added N or P, it is possible that these elements were not limiting and that Si, trace elements, and the components of soil extract were limiting. However, one of the dominant diatoms, Rhizosolenia, failed to grow at all. It is interesting

that the dinoflagellate Gymnodinium succeeded the diatom growth or appeared quite late in the experiment. This is reminiscent of the way in which dinoflagellates succeed diatoms during the summer in temperate waters. Presumably diatoms or their decomposition products supply some nutritional factor to dinoflagellates. Bacterial turbidity apparently prevented most phytoplankton from growing in the two treatments containing purines, pyrimidines, or amino acids.

In this experiment two of the three dominant diatoms (Nitzschia and Chaetoceros) and one of the two dominant dinoflagellates (Gymnodinium) grew. These three organisms have been carried through several subcultures in the complete medium made up with the original sea water and have now been inoculated into various enriched sea water media in routine use at Scripps. All three algae were successfully brought back from SCOT Expedition and are growing in our culture room.

TABLE 1

Growth of pelagic phytoplankton after the addition of nutrients to water samples collected at 10 m depth at SCOT Station 49 ("Dome")

Addition	D a y s

Organisms observed microscopically:

(If no symbol, none were seen)
 Ni = Nitzschia
 Ch = Chaetoceros
 G = Gymnodinium
 F = unidentified small flagellates

Animals from Night-Light Collections (W. L. Klawe)

The results of the dipnetting under the night light (see methods) are shown in table 2. An effort to classify to the specific level was made only in the case of juvenile tunas. Tunas collected during this expedition are: Katsuwonus pelamis, Euthynnus lineatus, and Auxis thazard. Organisms which were observed and recognized beyond any doubt, but not collected, are included in this table. Most of the fish caught under the night light were juvenile forms, but this is not true in all cases as many Myctophidae, Hemiramphidae, Exocoetidae, and some others were adult individuals. One animal has been omitted from the table. It is the ubiquitous Halobates which was observed at all night stations.

PROCEDURES

Regular Forenoon Stations

At approximately 1030 (local time) each day a station was occupied. The general procedure at these stations was as follows:

1. 900 ft bathythermograph lowering accompanied by general weather observations.
2. Nansen bottle cast to a depth of approximately 1000 m. The water samples were employed for the determination of salinity, oxygen and inorganic phosphorus, all of which were analyzed on shipboard.
3. 50-0 m phytoplankton net haul. A 17-cm truncate net with a mesh size of 32μ was employed.
4. Two plastic sampler casts, each to a depth of about 100 m. The samples were used for productivity studies and for chlorophyll a determinations.
5. Oblique zooplankton meter-net tow to a depth of about 300 m.
6. Surface zooplankton meter-net tow.
7. Submarine photometer lowering, to approximately 100 m.

Regular Night Stations

It was the practice to occupy a station each night,

generally commencing at midnight (local time). The general procedure was as follows:

1. Oblique nekton net tow to depth of about 90 m.
2. Oblique zooplankton meter-net tow to a depth of about 300 m.
3. Surface zooplankton meter-net tow.
4. Dipnetting under night light, when conditions were favorable.
5. 900 ft bathythermograph lowering with surface salinity sample and general weather observations. (Sometimes omitted.)

In Situ and Other Special Stations

The above-mentioned routine, one forenoon and one night station per day, was modified in a number of areas, as follows:

1. In situ productivity stations (Nos. 4, 23, 49, 56, 62, 88) were essentially extended forenoon stations. The extra operations were in situ measurement of productivity (C^{14} method) and horizontal closing-net zooplankton tows at three depths (in mixed layer, in thermocline, and below thermocline at about 100-200 m).
2. Island surveys. For the purpose of investigating zooplankton standing crop gradients near islands in the way described above (Summary of Preliminary Results), several stations were occupied for the sole purpose of making zooplankton and/or nekton net tows (9, 11, 12, at Clarion Island; 19-21, 24-26, at Clipperton Island; 52, 53, 55, at Cocos Island); in addition to stations which were regular forenoon, night, or in situ stations (8, 10, 13, at Clarion; 22, 23, 27, at Clipperton; 51, 54, 56, at Cocos). Bathythermograph lowerings were made at some of these special stations.
3. Gulf of Tehuantepec survey. Several stations were occupied in this area for the purpose of making Nansen bottle casts and zooplankton net tows only (78, 80, 82, 84, 87, 89, 91-94); in addition, three regular forenoon stations (79, 83, 86), one in situ productivity station (88), and four regular night stations with Nansen bottle cast added (77, 81, 85, 90) were occupied. Bathythermograph lowerings were made at all the

4. Tuna larva survey, Acapulco-Las Tres Marias. Stations 99-112 and 117-140, with the exception of 100, 104, 109, 122, 133, and 139 which were regular noon stations, were occupied for the purpose of making zooplankton net tows, bathythermograph lowerings, and GEK measurements only. The oblique meter-net tows were made to a depth of about 140 m.
5. Miscellaneous special stations, of which particulars are given subsequently in this report, were Nos. 38-41, 43, 44, 63-68, 97, 98, 113-116, 141, 142, 144, 146, 148.

Underway Routine

While underway between forenoon stations, 900-ft bathythermograph (BT) lowerings were made every three hours and were accompanied by weather observations. GEK observations were initiated on departure from Clipperton Island at 4-hour intervals and were continued more or less routinely throughout the remainder of the expedition.

Continuous Observations

1. Sea-surface temperature was continuously recorded with a Taylor thermograph.

2. Incident solar radiation was measured with a 10-junction Eppley pyrhelimeter combined with a Speedomax 0-10 mv recorder.
3. Depth of sea was continuously recorded with a Precision Depth Recorder.

METHODS

The following notes refer to kinds of observations in the order in which they appear in the "Station Data" and subsequent sections of this report.

Weather Observations

A hyphen indicates a missing observation. Wind force is given according to the Beaufort scale. The entry "weather" is given according to the code accompanying the Bathythermograph Observation Log published by the U. S. Navy Hydrographic Office. Cloud type, cloud amount (cover), and sea (height) are given according to codes in the Bathythermograph Observation Log, reproduced for convenience as follows:

<u>Code</u>	<u>Cloud Type</u>	<u>Cloud Cover</u>	<u>Sea Height</u>
0	Stratus or fractostratus	No cloud	Flat calm
1	Cirrus	Less than 1/10, or 1/10	Less than 1 ft
2	Cirrostratus	2/10 and 3/10	1 to 3 ft
3	Cirrocumulus	4/10	3 to 5 ft
4	Alto cumulus	5/10	5 to 8 ft
5	Altostratus	6/10	8 to 12 ft
6	Stratocumulus	7/10 and 8/10	12 to 20 ft
7	Nimbostratus	9/10 and 9/10 plus	20 to 40 ft
8	Cumulus or fractocumulus	10/10	40 ft and over
9	Cumulonimbus	Sky obscured	Very rough, confused sea

Temperature, Salinity, Density, Thermosteric Anomaly, and Dynamic Height Anomaly

Temperature was measured with standard reversing thermometers. Nansen-bottle spacing in the upper 150 m was determined by the thermal structure as shown by a BT, and an attempt was made to place bottles, in this part of the water column, at intervals of equal temperature rather than intervals of equal depth.

Two or more chlorinity determinations were made with each sample by the Knudsen method, and converted to salinity.

Processing of the data was carried out by the Data Collection and Processing Group, Division of Marine Resources, Scripps Institution of Oceanography, using the method of Klein (A new technique for processing physical oceanographic data. MS). The 125-m level was introduced into the integration to obtain greater accuracy in the determination of ΔD . The interpolated values at 125 m are not tabulated.

Temperatures from reversing thermometers are recorded in hundredths of a degree. Extrapolated values and values interpolated between remote observations are entered within parentheses. A hyphen indicates a missing observed value. The time is the time of messenger release. For Stations 62, 87 and 94, where two hydrographic casts were made, each messenger time and wire angle is given.

Three special notations have been used in listing these data.

To indicate a premature or delayed reversal of the bottle which results in certain depth and property errors, the following notation is used:

p: pretrip or posttrip.

Values which are not drawn through because they seem to be in error without apparent reason are indicated by one of the following notations:

r: rejected value (seems to be definitely wrong);

u: uncertain value (may be correct; occasionally it can influence the drawing of the property curve).

Additional surface temperature and surface salinity

data appear in the "Summary of Bathythermograph Observations."

Inorganic Phosphorus

Phosphate concentrations were measured using the method of Wooster and Rakestraw (Jour. Mar. Res., 10 (1): 91-100, 1951). Duplicate samples were analyzed at each depth and averaged, provided the calculated concentrations agreed within 0.05 $\mu\text{gm-at PO}_4/1$. Where agreement was less close both values were tabulated.

Reagent blank values (distilled water) between Stations 4 and 30 were rather variable with some exceedingly high. There was, however, no indication that the sea water determinations themselves were unreasonable or particularly in error. Thus a blank value was chosen after examining the order of reagent blank values obtained on the remainder of the expedition and the few reasonable values obtained between Stations 4 and 30. This selected blank value was used to correct all of the data between Stations 4 and 30.

Dissolved Oxygen

Dissolved oxygen measurements were made using the Winkler technique according to the directions of Wooster (Methods in chemical oceanography employed in the California Cooperative Sardine Research Program. Scripps Inst. Oceanogr., Tech. Rep., 27 pp.).

Submarine Daylight

At each forenoon station between Stations 4 and 95, both upwelling and downwelling radiation were measured with flat plate (i. e., cosine) collectors while only downwelling radiation was measured between Stations 122 and 147. Wratten No. 45 filters were used exclusively (peak transmission at 480 m μ) on the deck cell and on the submarine cells. Observations were not made at Stations 8, 13, 100 and 109 for technical reasons.

The station data have been corrected in the following manner:

- a. All data have been corrected for departure in linearity of response.
- b. In turn the values at each station have been

adjusted to a constant but arbitrary incident radiation value.

- c. Maximum instrument depth was frequently obtained from a BT or Vibrotron depth element attached to the photometer. Intermediate depths were calculated from wire angle/wire length relationship. Agreement between the maximum (usually about 100 m) computed and observed depths was fair (± 3 m) providing the wire angle remained under 45° . Whenever the wire angle exceeded 45° , depth determinations obtained by the two methods rarely agreed, the wire angle/wire length determinations almost always indicating that the maximum instrument depth was less than that shown on the BT. In such cases the maximum depth indicated by BT or Vibrotron was used and the intermediate depths were calculated from wire angle/wire length relationship if the wire angle was less than 45° ; in the few cases where the wire angle exceeded 45° , intermediate depths were rather arbitrarily chosen using a variety of subjective and objective criteria.
- d. The diffuse attenuation coefficient per meter was calculated for both downwelling and upwelling radiation using the following formula:

$$K = \frac{\ln I_{\lambda Z_1} - \ln I_{\lambda Z_2}}{Z_2 - Z_1}$$

where I is the corrected output of the submerged cell, Z is the depth in meters, and λ refers to the spectral sensitivity of the Photronic cell-filter combination employed (assumed to be a constant).

At a number of stations the ratio of upwelling to downwelling radiation, alpha (α), is given. In these computations the difference in sensitivity of the up-looking and downlooking cells was taken into account.

Incident Solar Radiation

A gimbals-mounted Eppley 10-junction pyrhelometer was mounted above all superstructure on the A-frame of the ship. The signal was recorded with a 0-10 mv Speedomax recorder. The daily curve was integrated with a planimeter. The daily incident radiation total and day length are given in the station data section of

this report, under the Regular Forenoon Station or In Situ Productivity Station of the day (occasionally under a Special Station).

Chlorophyll a Standing Crop

The water samples used for the determination of chlorophyll a content were collected from the surface with a plastic bucket; subsurface samples were collected with a Van Dorn-type plastic sampler. The water sample, 3.0-6.0 l in volume, was shaken after the addition of a small amount of magnesium carbonate, and filtered through a plain white 47-mm type HA Millipore filter. The filter membranes were dried in a vacuum desiccator with silica gel for 18-20 hours and then extracted with 3 ml of 90 percent acetone (glass redistilled) in the cold (ca. 10°C) and dark for approximately 10-12 hours. The sample was then centrifuged until clear. The supernatant was next decanted into a volumetric flask or cylinder and the remaining precipitate in the tube resuspended with 1-2 ml of 90 percent acetone, centrifuged, and the supernatant combined with that obtained previously. Recentrifugation of the combined extracts was frequently necessary to reduce turbidity. This extract was finally diluted to 6 ml, and its optical density was measured in a 10 cm semicro-absorption cell at 750, 665, 645, and 630 $m\mu$ with a Beckman model DU Spectrophotometer. Turbidity corrections were made on the basis of the sample transmission at 750 $m\mu$ and the concentrations of chlorophyll are calculated from the equations of Richards with Thompson (Jour. Mar. Res., 11 (2) pp. 156-172, 1952).

The integrated chlorophyll a value given at the bottom of the table for each station ("water column" value) was obtained by integration with a polar planimeter of smoothed profiles.

Zooplankton Standing Crop

Measurements by volume of the standing crop of zooplankton were made by means of plankton net hauls, using equipment comparable to that currently used in the California Cooperative Oceanic Fisheries Investigations. Both types of nets employed (regular and closing type) had a mouth-diameter of one meter; the main body of the net was made of 30XXX nylon grit gauze, while the rear section and cod end consisted of 56XXX nylon grit gauze. A flowmeter, mounted in the center of the mouth of each net, measured the volume of water filtered during each tow. Flowmeters were calibrated before and after the expedition.

Hauls made with non-closing nets were of three kinds: oblique, surface horizontal, and subsurface horizontal. Most oblique hauls were made by lowering the net at 50 m/min until 450 m of wire had been paid out and retrieving at the rate of 20 m/min. The ship speed was varied so as to maintain a wire angle of 45° during the retrieving period and the average haul lasted about 32 minutes. Between Acapulco and Tres Marias the majority of oblique net hauls were made by paying out only 200 m of wire; the duration of these hauls averaged about 14 minutes. The depths for individual hauls, estimated from wire angle and wire out, are given among the Station Data in this report, as are the times. The surface (0 m) horizontal tow was made astern while the oblique haul was in progress from the starboard side; it is estimated that the net did not sink more than 5 m during any tow of this type.

In a few localities (Stations 9, 11, 21, 26, 53, 55) where the depth did not permit even the shallow oblique haul mentioned above, a subsurface shallow horizontal haul was made. The net was lowered to a depth close to the bottom and towed horizontally. These computed depths ranged from 12 to 63 m.

The closing net (see Laevitt, Biol. Bull., 68 and 74, 1935 and 1938) was lowered to the desired depth and opened there by lowering a messenger, after which a horizontal haul was made. At the end of the haul, before it was brought to the surface, the net was closed by means of another messenger.

The catches were preserved in 4 percent buffered formalin. They were later filtered and the total "wet" volumes measured by displacement on shipboard. The volume of water sampled by each haul was determined by a method described by the South Pacific Fishery Investigations (now Biological Laboratory, Bureau of Commercial Fisheries, La Jolla), U. S. Fish Wildl. Serv. Spec. Sci. Rep.--Fish., No. 100, and the displacement volumes were converted into terms of the volume of organisms, in ml, collected from each 1000 m³ of water strained. The small organisms (see right-hand column, station zooplankton tables) are those whose lengths are less than 5 cm.

Nekton Standing Crop

The large zooplankton and small nekton (organisms from 0.5 to 10.0 cm long, approximately) were captured in what was essentially a very large coarse-meshed plankton net hauled obliquely at about 5 kt.

The net (about 20 ft in over-all length, of Marion Textiles pattern 467 nylon, throughout) was fastened at the mouth to a 5-ft-square iron frame to which towing bridles and weights were attached to keep it upright in the water when under way; a detachable cod end (as used on the meter nets, 56XXX nylon grit gauze) formed the catching part of the assembly.

The usual procedure on SCOT, where this net was employed mainly at night stations, was to pay it out on 450 m of 3/8 in. wire at 25 m/min and retrieve it at 10 m/min, all at a ship speed of 5 kt, 63 min in all for the haul. Depth, found for 12 hauls by attaching a BT, ranged from 72 to 115 m, mean 90 m.

Data recorded for these hauls consist of starting and finishing times, depth (where measured), and total displacement volume of catch.

Subsurface shallow (10-20 m) horizontal hauls with the same net were made at a few stations (9, 11, 19, 21, 53, 55) where the depth did not permit the oblique type of haul described above.

Night-Light Observations

At night stations, when weather permitted, an electric light (500 w) was placed above the water from the stern of the drifting vessel. A fine-meshed dipnet was used to capture young tunas and an array of other organisms under the light. Usually the light was left on for about 30 minutes but there were occasional large deviations from that period.

Bathythermograph Observations

The list of bathythermograph (BT) observations has been compiled from information tabulated on BT prints by the Scripps Institution BT Section. It includes: surface temperature; class of temperature-depth trace (C, M, N, or P, according to U. S. Navy Hydrographic Office criteria); and depth of surface layer (SL), defined as depth from surface to top of sharp negative temperature gradient (or depth of maximum temperature if there is a positive temperature gradient). Surface salinity, determined by the Knudsen method, is entered for BT positions at which it was measured.

Surface Current Velocity and Direction (GEK)

All measurements were made with neutrally buoyant cable. The conversion from measured electrical

potential to surface current was by the formula $E = -VH_zS$ where E is the measured potential, V the surface current, H_z the vertical component of the earth's magnetic field, and S the interelectrode distance. No corrections, therefore, have been made for "depth of current," "electrode droop," or "windage on electrodes."

Primary Production

Due to a number of technical difficulties, the productivity data could not be completed in time to be included in this report. These data will appear in the next report in the form of an appendix. The productivity techniques employed on SCOT are given below for reference.

The carbon-14 method was employed in these studies to determine the rate of carbon fixation by the phytoplankton. The carbon-14 solution was prepared and standardized in the manner described by Steemann Nielsen (*Jour. du Cons.*, 18 (2): 117-140, 1952) with the exception that glass redistilled water rather than artificial sea water was used as the solvent. The C^{14} solution was then filtered through an HA Millipore filter and put in 10-ml glass ampules which were immediately autoclaved. The C^{14} solution was added with a plastic syringe and stainless steel needle provided with a positive stop. The radioactivity of the samples was measured with an NMC-PC#1 proportional counter.

All of the pyrex bottles used for incubation in these studies were aged in sea water and after use were washed with a detergent followed by an acid (HCl) and sea-water rinse. Immediately prior to drawing of the sample, each bottle was rinsed three or more times with sea water collected at the sample depth.

In situ surface productivity was measured using samples dipped from the sea surface with a plastic bucket at either sunrise or local noon. The samples were placed in clean, well-aged, 250-ml or 125-ml Pyrex bottles inoculated with C^{14} , and trailed astern of the vessel, just under or on the top of the sea surface, until local noon or sunset, respectively. The samples were filtered immediately and placed in a vacuum desiccator for drying.

The in situ vertical measurements of productivity were carried out in the following manner. A water sample was collected at each desired depth with the plastic Van Dorn-type sampler shortly before daylight. The samples were transferred to clean, well-aged, 125-ml Pyrex bottles and the C^{14} solution injected with a plastic hypodermic syringe and stainless steel needle. The samples were resuspended at or slightly before dawn, at approximately the depth at which they were collected, on a weighted rope supported by a free-floating glass buoy (14 in. in diameter) enclosed in a cord netting and attached to a bamboo pole bearing a flag and radar reflector at its top. The surface sample was attached to the side of the glass buoy, just under the sea surface. The samples were collected at noon, local time, and were promptly filtered and dried for counting.

The samples incubated on shipboard were inoculated with C^{14} in the same manner as the in situ and trailing bottle material. The incubator itself was similar to that employed by Steemann Nielsen (*op. cit.*). Temperature control was achieved by circulating subsurface sea water through the water bath at a rate of 4-6 l. per minute. The temperature in the bath fluctuated somewhat but never exceeded the sea-surface temperature by more than 2.3°C , and usually by less than 1°C . Temperatures less than that of the sea surface were not observed in the incubator. The samples were illuminated by a bank of 10 daylight-type fluorescent lamps. The lamp bank was moveable and was the means employed in keeping the intensity of light at the bottles at 1000 foot-candles.

SUMMARY OF SURFACE CURRENT (GEK) OBSERVATIONS

(Non-hyphenated fix numbers refer to station positions. Hyphenated numbers refer to observations between stations; e. g., 35-7 signifies 7th fix after Station 35.)

Current Fix No.	Date (1958)	Latitude (°N)	Longitude (°W)	Direction (°T)	Velocity (cm/sec)	Current Fix No.	Date (1958)	Latitude (°N)	Longitude (°W)	Direction (°T)	Velocity (cm/sec)
